## British Journal of Pharmacology and Chemotherapy

## 2 : June 1947

The absorption of some sulphaguanidine derivatives in mice. (F. L. Rose & A. Spinks) 65-78  
The effects of pyrimidine sulphonamide derivatives upon the blood-clotting system and testes of chicks and the breeding capacity of adult fowls. (F. D. Asplin & E. Boyland) 79-92  
The comparison of respiratory stimulant drugs. (R. H. Thorp) 93-99  
The biological estimation of substances used in treating cestode infestations. (P. Holtzen) 100-107  
The affinity of atropine-like esters for esterases. (H. Blaschko, T. C. Chou & I. Wajda) 108-115  
The inhibition of esterases by paludrine. (H. Blaschko, T. C. Chou & I. Wajda) 116-120  
Oxidation of adrenaline in alkaline solution. (G. B. West) 121-130  
The action of adrenaline, epinephrine and other substances on the refractory period of the heart. (J. I. H. H. H. H.) 131-142  
The inhalation of hexoestrol. (G. L. Foss & J. H. Gaddum) 143-148

## 2 : September 1947

2-p-Aminobenzenesulphonamido-4: 6-dimethoxy-pyrimidine: experimental evaluation. (J. C. Gage, A. R. Martin, F. L. Rose, A. Spinks & G. A. P. Tucey) 149-162  
2-p-Aminobenzenesulphonamido-4: 6-dimethoxy-pyrimidine absorption and excretion in man. (H. G. L. Bevan) With notes on a clinical trial in pneumonia. (R. W. Luxton) 163-168  
An assessment of the value of suggested therapies for leucopenia. (H. Cullumbine) 169-172  
Selective inhibition of pseudo-cholinesterase by diisopropyl fluorophosphonate. (R. D. Hawkins & B. Mendel) 173-180  
A preliminary report of the toxicity and the associated blood concentrations of paludrine in laboratory animals. (R. Butler, D. G. Davey & A. Spinks) 181-188  
A new scale for the measurement of drug antagonism. (H. O. Schild) 189-206  
Some actions of  $\beta$ -hydroxy- $\alpha$ - $\beta$ -diphenylethylamine. (C. B. B. Downman) 207-216  
The therapeutic action of some known amoebicides in rats. (W. R. Jones) 217-220

## British Journal of Physical Medicine

## 10 : May-June 1947

Physical medicine and the rheumatic diseases. (F. Bach) 66-69  
Man-power deployment. (G. T. L. F. Morris & J. E. A. King) 70-74  
Electromyography in clinical medicine. (P. Bauwens) 75-78  
The septic hand treated with high-dosage infrequent penicillin injections. (G. P. B. Whitwell) 78-80  
Anxiety and muscle tension. (W. Barlow) 81-87

## 10 : July-August 1947

Physical medicine and gynaecology. (G. E. Hesketh) 98-101  
The prophylaxis of industrial strains. (G. C. Pether) 102-106  
The physical treatment of mental illness. (A. Pool) 106-115  
Rehabilitation of the chronic arthritic. (M. H. L. Desmarais) 116-118  
Analysis of function. (H. E. Griffiths) 119-120

## British Journal of Radiology

## 20 : June 1947

The jubilee of the Röntgen Society. (A. E. Barclay) 221-222  
Interpretation of children's chest X rays. (L. G. Blair) 223-237  
A note on the use of the Lysholm skull table. (D. Gordon) 238-239  
A quantitative analysis of the direct and indirect action of X radiation on malignant cells. (I. Lasnitzki) 240-247  
A device to facilitate the production of X-ray isodose curves. (R. G. Mitchell) 248-252  
Traumatic aneurysm following a stab wound. (A. H. N. Welikala) 256

## 20 : July 1947

The radiotherapist and the cancer patient. (D. W. Smithers) 261-268  
Symposium: radiation necrosis. (A. H. McIndoe, R. Forbes & B. W. Windeyer) 269-278  
Radiation doses received by the skin of a patient during routine diagnostic X-ray examinations. (J. H. Martin) 279-283  
Two diagrams for the computation of dosage rates from linear radium sources. (F. Bush) 284-287  
The early radiological diagnosis of ankylosing spondylitis. (G. L. Rolleston) 288-293  
Upper cervical vertebral anomaly. (A. A. Vickers) 294  
Extensive calcification of the falx cerebri. (A. H. N. Welikala) 295-296

## 20 : August 1947

The tolerance dose and the prevention of injuries caused by ionizing radiations. Silvanus Thompson Memorial Lecture. (R. M. Sievert) 306-318

The radiograph from the physicist's viewpoint. (G. Spiegler) 319-325  
The technique of direct (percutaneous) cerebral angiography. (E. Lindgren) 326-331  
Cranio-cleido-dysostosis. (F. L. Ingham) 332-334

## 20 : September 1947

Further observations on fracture of the first rib. (B. R. Alderson) 345-359  
A case of osteo-pikilosis. (R. Fawcitt) 360-362  
Arteriography of the limbs. A brief study of its value in arterial injuries. (J. L. Feuchtwanger) 363-367  
Experiments on the mechanism of the biological action of fast neutrons, using the summation method for lethal effects in mice. (With a section on dosimetry of fast neutrons.) (J. S. Mitchell) 368-380  
Quantitative histological analysis of radiation effects in human carcinomata. (B. Wolff & F. Ellis) 381-386  
A portable processing tank for mass miniature radiography. (A. E. Beynon) 387-388

## British Journal of Social Medicine

## 1 : January 1947

Incompatibility of mother and foetus with respect to the iso-agglutinin A and its antibody. (I. A. H. Waterhouse & I. Hapeman) 1-17  
A documentary study of the treatment and blood transfusions. (P. L. McKinlay) 33-50  
Epidemiology of the haematology of 663 substandard recruits under training at an army physical development centre. (R. A. M. Case) 51-72

## 1 : April 1947

Studies on infant mortality. II. (B. Woolf) 73-125  
Variations in occupational mortality between and within the social classes. (I. Sutherland) 126-134  
Mental illness among army officers. (W. W. Roberts & J. N. P. Moore) 135-147

## British Journal of Surgery

## 34 : April 1947

Injuries of peripheral nerves in two world wars. (W. R. Bristow) 333-348  
Penicillin therapy in late infected compound fractures from Burma. (H. R. H. Harley, J. H. Bowie & M. D. Borcar) 348-353  
Partial gastrectomy for simple ulcer: a review of the end-results of 132 cases, with a criticism of the Polya operation. (A. B. Watson) 353-366  
Professor G. Grey Turner at the Post-graduate Medical School. 366-373  
The parasympathetic supply of the distal colon. (J. Lannon & E. Weller) 373-378  
A statistical study of 1405 cases of cancer of the stomach. (W. L. Harnett) 379-385  
Lesion of the intervertebral disk caused by lumbar puncture. (A. H. Baker) 385-388  
A report on four cases of congenital genu recurvatum occurring in one family. (A. L. McFarlane) 388-391  
The surgical pursuit and removal of a metallic foreign body from the systemic venous circulation. (W. W. Davey & G. E. Parker) 392-395  
The elimination of "apparatus inertia" in the treatment of fractures. (G. F. Donmisse & E. J. Nangle) 395-402  
The solitary ectopic pelvic kidney: with reports of two further cases. (H. G. Hanley & W. A. Steel) 402-407  
A survey of the incidence of inguinal hernia in different racial groups. (A. I. L. Maitland) 408-410  
Bone abscess from human bite: report of a case. (A. T. Andreasen) 411-414  
Ligature of aortic arch in the neck. (T. E. D. Beaven & L. Fatti) 414-416  
Granuloma of the Fallopian tube due to surgical glove talc: silicious granuloma. (G. B. S. Roberts) 417-423  
An operation for nerve pedicle grafting: preliminary communication. (F. G. St. C. Strange) 423-425

## British Journal of Tuberculosis and Diseases of the Chest

## 41 : April 1947

Intestinal tuberculosis: some observations. (R. Y. Keers) 33-37  
An obscure case of lymphadenopathy with pulmonary fibrosis. (M. Davidson & L. R. W. Price) 38-42  
The significance of the negative tuberculin test. (B. Coutts) 42-48  
Miliary carcinoma of the lung. (C. F. Hawkins) 48-51

## British Journal of Venereal Diseases

## 23 : March 1947

The effects of penicillin administration on menstrual and other sexual cycle functions. (A. E. W. McLachlan & D. D. Brown) 1-10  
Commercial penicillins and the treatment of syphilis: some recent American developments. (R. R. Willcox) 11-14  
The evolution of syphilis after small doses of penicillin: a critical survey. (E. Cronin) 15-19  
Venereal diseases in the British-occupied zone of Germany. (F. R. Curtis) 20-30  
A discussion on penicillin therapy in venereal diseases in women. 31-39  
Local penicillin in lymphogranuloma inguinale. (G. O. Mynne & A. D. Bain) 40  
Acute encephalopathy and arsenotherapy of syphilis. (J. S. McCann) 41-43

## British Medical Journal

## 1 : 7/6/47

Centennial of the American Medical Association. (M. Fishbein) 795-798  
The sulphone treatment of leprosy. (E. Muir) 798-801  
Tropical eosinophilia in East Africa. (H. T. H. Wilson) 801-804  
Causalgia of the face: two cases successfully treated by sympathectomy. (J. A. W. Bingham) 804-805  
In-patient treatment of the maladjusted child. (E. G. W. Barker & W. L. Milligan) 805-807

## 1 : 14/6/47

- The measurement of human skill. (F. C. Bartlett) 835-838  
 A conception of industrial health. (R. C. Browne) 838-842  
 Surgical emphysema due to compressed air. (A. M. Desmond) 842-843  
 Digital foreign bodies in spot-welders. (W. A. B. Reynard & F. Smith) 843-847  
 Symmetrical gangrene in the African. (M. Gelfand) 847-849

## 1 : 21/6/47

- Social and occupational factors in the aetiology of skin cancer. (J. A. Ryle & W. T. Russell) 873-877  
 The measurement of human skill. (F. C. Bartlett) 877-880  
 Modern treatment in psychological medicine. (L. Minski) 880-884  
 Penicillin in the treatment of diphtheria. (D. A. Long) 884-886  
 Splints for fractured noses. (M. C. Oldfield & W. R. Roberts) 886-887

## 1 : 28/6/47

- Recent advances in the physiology of vision. Part II. (H. Hartridge) 913-916  
 On complete removal of the prostate: a preliminary communication. (H. S. Souttar) 917-918  
 A new euphoriant for depressive mental states. (G. T. Stockings) 918-922  
 Type I triple cardiac rhythm in normal hearts: a study of 1,360 naval recruits and personnel. (P. J. O'Meara) 922-925  
 Severe erythema multiforme. (I. B. Sneddon) 925-927

## 2 : 5/7/47

- An inquiry into the epidemiology of pemphigus neonatorum. (V. D. Allison & B. C. Hobbs) 1-7  
 Gall-bladder complications following resection of stomach for peptic ulcer. (C. L. H. Major & T. J. J. Suren) 8-11  
 Diathermy dissection of the gall-bladder. (R. J. M. Love) 11-13  
 The longest span of life based on the records of centenarians in England and Wales. (V. Korenehevsky) 14-16  
 The Foundling Hospital child welfare scheme. (D. H. Geffen) 23

## 2 : 12/7/47

- Choice of drugs in the treatment of duodenal ulcer. (A. H. Douthwaite) 43-47  
 Bornholm disease in the tropics. (W. M. Jamieson & D. M. Prinsley) 47-50  
 A note on the causation of sudden death. (R. Richards) 51-53  
 Hemiplegia in young adults. (G. J. Dixon) 53-54  
 Stress fracture of a metatarsal in a young child. (L. D. Rutter) 55  
 Prevention of peritoneal adhesions by transplantation of amnion. (A. Kuhany) 55-56  
 Bilateral chronic suppurative otitis media with complications. (A. M. Ross) 56

## 2 : 19/7/47

- Some aspects of human infertility. (A. Sharman) 83-87  
 Lymph-gland biopsies for suspected bone and joint tuberculosis: an analysis of 100 consecutive cases. (G. P. Arden & J. C. Scott) 87-89  
 The treatment of inevitable, incomplete, and septic abortion: an analysis of 600 consecutive cases. (J. M. Corston & J. Stallworthy) 89-91  
 Work of a tuberculosis contact clinic for young children, 1941-5. (F. J. W. Miller) 91-94  
 Rhabdomyosarcoma causing acute retention in infants. (E. Minchin) 94-95  
 Tuberculosis and the Health Act. Mr. Aneurin Bevan at Anti-Tuberculosis Conference. 103-106

## 2 : 26/7/47

- Medicine in the post-war world. (H. Lett) 121-123  
 Surgical aspects of amoebiasis. (P. Theron) 123-126  
 Iodine and failing lactation. (M. Robinson) 126-128  
 Acute dilatation of the stomach. (B. Markowski) 128-130  
 Bile peritonitis in infancy. (F. D. Hindmarsh) 131  
 The Berger-Kahn test for syphilis. (J. H. Fodden & E. J. Maddox) 131-132  
 Cine-radiography in orthopaedic surgery. (L. Gillis) 140-141  
 Acute poliomyelitis. 141-142

## 2 : 2/8/47

- The part of chemistry in the new therapeutics. (H. Dale) 161-164  
 Anomalous manifestations of malnutrition in Japanese prison camps. (R. G. S. Whitfield) 164-165  
 Temporal or giant-cell arteritis. (K. Robertson) 168-170  
 Anastomotic ulcer 12 months after Somervell operation. (H. Dodd) 170-171  
 The combined action of phenobarbitone and epanutin. (D. Blair) 171-174  
 Nomograms for relative humidity. (G. H. Bell & J. B. de V. Weir) 174  
 Recent Canadian research on insulin. Prof. Charles Best's Banting Memorial Lecture. 183-184  
 Future hospital administration. Sir Arthur Rueker's address. 184-186

## 2 : 9/8/47

- Liver function tests in the diagnosis of jaundice: a review of 200 cases. (N. F. MacLagan) 197-201  
 Relative oral toxicity of some therapeutic iron preparations. (G. F. Somers) 201-203  
 An experiment in rehabilitation. (J. R. Napier, J. N. Barron, T. P. Gregory & D. R. Thompson) 203-206  
 Acquired syphilis in children. (M. Murrell & M. S. Gray) 206-207  
 Factors influencing the future provision of day nurseries: long-term policy. 207-210  
 A possible mode of action of penicillin. (K. M. Pandalai & M. George) 201-211  
 Surgery in two wars. (P. H. Mitchiner) 219-220  
 French railway (Northern Region) X-ray train. (P. Le G6) 221-222

## 2 : 16/8/47

- The problem of fertilization. (Rothschild) 239-242  
 Influence of penicillin on the coagulation of blood: with especial reference to certain dental operations. (A. Fleming & E. W. Fish) 242-243  
 Irradiation of gastric cancer. (G. C. Fairchild & A. Sborter) 243-247

- Field investigation of an outbreak of diphtheria. (J. W. Webb & N. Macfadyen) 248-249  
 Partial hepatectomy and right hemicolectomy for carcinoma of the hepatic flexure. (R. W. Raven) 249-250  
 Hernia of the diaphragm as a complication of labour. (B. C. Murless) 251-252  
 A new treatment of rheumatoid arthritis. (L. Barsi) 252-253  
 Contact lenses. (C. G. K. Sharp) 261-262

## 2 : 23/8/47

- Chronic hypertension and pregnancy. (F. J. Browne) 283-287  
 Further observations on the production of canine hysteria by flour treated with nitrogen trichloride (agene process). (E. Mellanby) 288-289  
 Perforated peptic ulcer: short-term variations in frequency. (R. A. Jamieson) 289-291  
 Some clinical observations on the present outlook of acute poliomyelitis. (W. H. Kelleher) 291-295  
 Artificial circulation produced by rocking: its use in drowning and anaesthetic emergencies. (F. C. Eve) 295-296  
 Poisoning by *Incocybe fastigiata*. (D. Wilson) 297  
 Some edible fungi. (J. Ramsbottom) 304-305

## 2 : 30/8/47

- The early treatment of poliomyelitis. (H. J. Seddon) 319-321  
 Penicillin therapy in ophthalmia neonatorum. (A. Sorsby) 322-327  
 A fatal case of acute porphyria with unusual features. (A. Abrahams, C. J. Gavey & N. F. MacLagan) 327-329  
 Hypoglycaemia following partial gastrectomy. (J. A. L. Gilbert & D. M. Dunlop) 330-332  
 Status epilepticus complicating pregnancy. (J. F. Goodwin & C. W. Lawson) 332-333  
 Discontinuous intravenous infusion and transfusion. Advantages and technique. (H. Bailey) 333-334  
 A medical jubilee in Central Africa. (R. T. S. Goodchild) 342-344

## 2 : 6/9/47

- The General Medical Council and medical education. (H. L. Eason) 359-363  
 Psychology in medical education. (J. Rickman) 363-366  
 Statistics in the medical curriculum? (A. B. Hill) 366-368  
 The future of public health education. (J. M. Mackintosh) 368-371

## 2 : 13/9/47

- The early diagnosis of cancer of the oesophagus and stomach. (H. Ogilvie) 405-407  
 Public health—Berlin, 1946. [Abridged] (J. Melvin) 407-410  
 Changes in blood phosphate after ingestion of glucose and fructose in sprue. (L. P. R. Fourman) 411-413  
*H. influenzae* meningitis in relation to treatment: a clinical study of four cases. (J. Thomson, L. M. Bruce & M. G. Green) 414-416  
 Balantidial dysentery in Rodriguez and its treatment with mercury binitride. (M. Shun-Shin) 417-418  
 Recruitment and training of nurses. Report of working part. 426-427  
 Changes in food consumption. 427-428  
 International Conference of Physicians. First post-war assembly in London. 430-431

## 2 : 20/9/47

- Haematemesis and melaena with special reference to bleeding peptic ulcer. (F. A. Jones) 441-446  
 Gastro-enteritis of unknown aetiology. An outbreak in a maternity unit. (G. T. Cook & B. P. Marmion) 446-450  
 Suppurative arthritis of hip-joint treated with penicillin: report of four cases. (K. J. Gilchrist) 450-451  
 Treatment of varicose veins. Possible danger of injection of sclerosing fluids. (A. M. Boyd & D. J. Robertson) 452-454  
 Penicillin by intra-oral drip. (G. R. Royston) 454-455  
 International Conference of Physicians. Surgery of congenital heart disease. 462-465  
 International Society of Surgery. Twelfth Congress in London. 466-467

## 2 : 27/9/47

- Haematemesis and melaena: with special reference to bleeding peptic ulcer. Part II. (F. A. Jones) 477-482  
 Rheumatoid arthritis and amyloid disease: report of a case. (W. Yeoman & J. V. Wilson) 483-485  
 Congenital defect of left diaphragm with volvulus of stomach and transposition of viscera. (E. Owen-Lloyd & D. Roberts) 485-487  
 Military appearances in the lungs in mitral stenosis: endogenous pulmonary haemosiderosis. (T. E. Gumpert) 488-489  
 A case of pineal cyst. (S. Sevi & J. Schorstein) 490-491  
 Amyoplasia congenita associated with hyperostosis frontalis interna. (R. N. Herson) 491-492  
 Tuberculosis of the great trochanter. (B. McMurray) 492-494  
 Acute interstitial polymyositis treated with penicillin. (I. Friedmann & F. Por) 494-495

## Bulletin of Hygiene

## 22 : June 1947

- Acute anterior poliomyelitis. A survey of present knowledge, with particular reference to the method of spread. (A. J. Rhodes) 353-385

## Clinical Science

## 6 : 1947

- The circulatory action of theophylline ethylene diamine. (S. Howarth, J. McMichael & E. P. Sharpey-Schafer) 125-135  
 The survival of transfused erythrocytes, with special reference to cases of acquired haemolytic anaemia. (P. L. Mollison) 137-172  
 Oliguria after abortion. (J. H. Humphrey & F. A. Jones) 173-186  
 Effects of oxygen, venesection and digitalis in chronic heart failure from disease of the lungs. (S. Howarth, J. McMichael & E. P. Sharpey-Schafer) 187-196

## Dental Record

67 : May 1947

Clinical trials of treating infected pulps with penicillin. (F. R. Munz) 115-125  
 Myths and fallacies in dental practice. (F. Coleman) 125-131

67 : June 1947

The philosophy of orthodontics. (B. R. Townsend) 140-147  
 Bone injections. (J. Angelman) 149-152  
 Ceramacyl jacket crown. (N. N. Bery) 152-154

67 : July 1947

Dental treatment for expectant and nursing mothers. (J. F. Pilbeam) 165-170  
 War-time experiences. "With the Royal Navy." (J. E. Daniels) 170-176  
 War-time experiences. "With the B.L.A. on 'D' Day." (J. P. Blunt) 176-178

## Guy's Hospital Reports

95 : 1946

The tragedy of Sbelley. (H. St. H. Vertue) 53-72  
 Arterio-capillary fibrosis: an historic specimen. (W. N. Mann) 73-78  
 Recurrent mastoiditis: a critical examination of the cortical mastoidectomy. (P. Reading) 79-87  
 Unheralded, fatal haemorrhages in haemangiomas of the brain. (C. F. Hawkins & R. E. Rewell) 88-91  
 Gangrene of the scrotum. (R. G. Robinson) 92-97

## Journal of Anatomy

81 : April 1947

The prostate gland of *Herpestes edwardsii edwardsii*. (M. A. H. Siddiqi) 123-126  
 The primary optic centres of the rat. An experimental study by the "Bouton" method. (W. J. H. Nauta & J. J. Van Straaten) 127-134  
 Absence of cell multiplication during degeneration of non-myelinated nerves. (J. Joseph) 135-139  
 Organization of the dorsal columns of the spinal cord and their nuclei in the spider monkey. (H. T. Chang & T. C. Ruch) 140-149  
 Topographical distribution of spinothalamic fibres in the thalamus of the spider monkey. (H. T. Chang & T. C. Ruch) 150-164  
 Cracking in the metacarpo-phalangeal joint. (J. B. Roston & R. W. Haines) 165-173  
 The histogenesis of the epidermis in the rat and mouse. (J. Hanson) 174-197

## Journal of Endocrinology

5 : April 1947

Antigonadotrophic activity in male rats. (J. Freud & I. E. Uylert) 59-67  
 Factors involved in maintaining involution of the thymus during suckling. (C. Grégoire) 68-87  
 Effects of prolonged oestrogen administration in female New World monkeys, with observations on a pericardial neoplasm. (R. Iglesias & A. Lipschutz) 88-98  
 Inactivation of chorionic gonadotrophin by X-rays. (A. Hochman, R. Black, G. Goldhaber & F. Sulman) 99-102  
 On the induction of diabetes by means of alloxan. (J. H. Gaarenstroom) 103-110

5 : July 1947

Fate of some oestrogenic phenanthrene and stilbene derivatives in the rat. (A. T. Nielsen, K. Pedersen-Bjergaard & M. Tonnesen) 111-114  
 Failure of lactogenic hormone to maintain pregnancy involution of the thymus. (C. Grégoire) 115-120  
 The influence of gonadal hormones on serum riboflavin and certain other properties of blood and tissues in the domestic fowl. (R. H. Common, W. A. Rutledge & W. Bolton) 121-130  
 Effect of 2-thiouracil on the histology of the normal human thyroid. (I. Doniach & E. P. Sbarpey-Schafer) 131-135  
 The neurovascular link between the neurohypophysis and adenohypophysis. (J. D. Green & G. W. Harris) 136-146  
 Leanness in adrenalectomized rats. (F. Schiffer & E. Wertheimer) 147-151  
 The instability of oestrogens in solution. (A. E. W. Smith & P. C. Williams) 152-157  
 The relation between direct and indirect oestrogenic function in a series of synthetic oestrogens. (G. Brownlee & A. F. Green) 158-165  
 Implants of synthetic oestrogens in the udders of sheep. (G. Peeters & L. Massart) 166-169  
 Halogen-substituted oestrogens related to triphenylethylene. (C. W. Emmens) 170-173  
 The effects of pregnancy and relaxin on the histology of the pubic symphysis in the mouse. (K. Hall) 174-182

## Journal of General Microbiology

1 : January 1947

Myxobacteria in soils and composts; their distribution, number and lytic action on bacteria. (B. N. Singh) 1-10  
 Studies on soil ascaridae. 1. Distribution of species of *Dictyastelium* in soils of Great Britain and the effect of bacteria on their development. (B. N. Singh) 11-21  
 The life cycle of sporing *Actinomyces* as revealed by a study of their structure and septation. (E. Klieneberger-Nobel) 22-32  
 A cytological study of myxococci. (E. Klieneberger-Nobel) 33-38  
 Differentiation of the vegetative and sporogenous phases of the actinomycetes. 1. The lipid nature of the outer wall of the aerial mycelium. (D. Erikson) 39-44  
 Differentiation of the vegetative and sporogenous phases of the actinomycetes. 2. Factors affecting the development of the aerial mycelium. (D. Erikson) 45-52

The assimilation of amino-acids by bacteria. 1. The passage of certain amino-acids across the cell wall and their concentration in the internal environment of *Streptococcus faecalis*. (E. F. Gale) 53-76  
 The assimilation of amino-acids by bacteria. 2. The action of tyrocidin and some detergent substances in releasing amino-acids from the internal environment of *Streptococcus faecalis*. With a note on electron micrographs of normal and tyrocidin-lysed streptococci. (E. F. Gale, E. S. Taylor, P. D. Mitchell & G. R. Crowe) 77-85  
 The assimilation of amino-acids by bacteria. 3. Concentration of free amino-acids in the internal environment of various bacteria and yeasts. (E. S. Taylor) 86-90  
 The toxins of *Clostridium oedematiens* (Cl. novyi). (C. L. Oakley, G. H. Warrack & P. H. Clarke) 91-107

1 : June 1947

*Bacterium melaninogenicum*—a misnomer. (H. Schwabacher, D. R. Lucas & C. Rimington) 109-120  
 The effect of temperature on the growth of *Bacterium coli* at pH 7.0 with a constant food supply. (R. C. Jordan & S. E. Jacobs) 121-136  
 A preliminary study of the formation, assay and stability of tyrothricin. (J. C. Appleby, E. Knowles, J. Pearson & T. White) 137-144  
 Production of antifungal and antibacterial substances by fungi; preliminary examination of 166 strains of Fungi Imperfecti. (P. W. Brian & H. G. Hemming) 158-167  
 A simple plate method for multiple tests of the antibacterial activity of many bacteria against other bacterial strains. (N. G. Heatley) 168-170  
 Microbiological aspects of the submerged-culture production of penicillin on a pilot-plant scale. (E. Grenfell, B. J. Legge & T. White) 171-186  
 Methods of penicillin production in submerged culture on a pilot-plant scale. (J. J. Gordon, E. Grenfell, E. Knowles, B. J. Legge, R. C. A. McAllister & T. White) 187-202  
*Clostridium aurantibutyricum* (n.sp.): a pink butyric acid *Clostridium*. (E. Hellinger) 203-210  
 Some properties of a thermolabile antigen of *Erysipelothrix rhusiopathiae*. (A. W. Gledhill) 211-220  
 The preparation of microtools for the micromanipulator. (A. C. Thaysen & A. R. Morris) 221-231  
 The routine examination for antibiotics produced by moulds. (N. G. Heatley & F. J. Philpot) 232-237  
 A selective medium for pleuropneumonia-like organisms. (D. G. ff. Edward) 238-243  
 The production of tyrothricin by submerged culture of *Bacillus brevis* in synthetic media. (J. C. Appleby, E. Knowles, R. C. A. McAllister, J. Pearson & T. White) 145-157  
 Some observations on the use of penicillinase in sterility tests for penicillin. (M. Pile, D. D. Stewart & A. F. B. Standfast) 244-250  
 The preservation of bacteria by drying. (Stamp) 251-265

## Journal of Hygiene

45 : May 1947

The nature of somatic phase variation and its importance in the serological standardization of O-suspensions of *Salmonellas* for use in the Widal reaction. (W. Hayes) 111-117  
 Craigie's Vi phase method and South African strains of *B. typhosus*, with special reference to typhoid carriers. (C. G. Crocker) 118-122  
 Separation and concentration of a thermolabile precipitinogen from *Shigella dysenteriae* (Shiga). (M. Shelubsky & L. Olitzky) 123-127  
 Bacterial infection and immunity in lower vertebrates and invertebrates. (K. A. Bisset) 128-135  
 Studies in the dynamics of disinfection. VIII. The effect of lethal temperatures on standard cultures of *Bact. coli*. I. A detailed analysis of the variations of death-rate with time. (R. C. Jordan, S. E. Jacobs & H. E. F. Davies) 136-143  
 Studies on the dynamics of disinfection. IX. The effect of lethal temperatures on standard cultures of *Bact. coli*. I. The nature of the probit-log survival-time relationship at pH 7.0. (R. C. Jordan, S. E. Jacobs & H. E. F. Davies) 144-148  
 Fatal meningitis due to a capsulated *Neisseria*. (A. L. M. Christie & G. T. Cook) 149-150  
 Bacteriological investigation of the washing and sterilization of food containers: a report to the Medical Research Council. (R. Knox & J. Walker) 151-158  
 Experiments on infection of cows with typhoid bacilli. (W. M. Scott & F. C. Minett) 159-168  
 Feeding and breeding of laboratory animals. IV. Breeding of rabbits without fresh green food. (H. M. Bruce) 169-172  
 Improved guns for the delivery of liquid D.D.T. spray and powder by mechanical compressors. (I. Gordon) 173-175  
 Mosquito repellents: being a report of the work of the mosquito repellent inquiry, Cambridge 1943-5. (S. R. Christophers) 176-231  
 A survey of tuberculosis in the industrial county of Lanarkshire, Scotland. (T. G. Brown) 232-238  
 The influence of social factors on the incidence of extrapulmonary tuberculous infection: an investigation of the environment of tuberculous patients in Lanarkshire, Scotland. (T. G. Brown) 239-250

## Journal of Laryngology and Otology

61 : July 1946

Ménière's syndrome: evidences for a vascular mechanism. (M. Atkinson) 344-366  
 Rupture of the tympanic membrane of blast origin. (F. B. Korkis) 367-390  
 A further report on the treatment of petrositis with penicillin. (P. Reading) 391-395  
 One hundred cases of post-cricoid stenosis followed up. (W. Kirchenberger & R. L. Flett) 396-398

61 : August 1946

Oto-rhinological problems of offensive diving. (S. Gay-French) 417-440  
 Fenestration of the labyrinth. Part II. Transtympanic fenestration. (O. Popper) 441-458  
 Fibro-angioma of the right ala nasi in a boy of two years. (C. de W. Gibb) 459  
 Royal Society of Medicine—Section of Laryngology. Discussion on rhinology in the Mediterranean and African areas. (J. P. Stewart) 460-470

## 61 : September 1946

- What can we deduce from quantitative estimations of bone conduction? (A. Tumarkin) 473-493  
 On directional hearing. (L. B. W. Jongkees & J. J. Groen) 494-504  
 The hearing level eleven years after partial intracranial division of the VIIIth nerve for vertigo. (W. S. Adams) 505-507  
 Royal Society of Medicine—Section of Otolaryngology. Discussion on war deafness and the care of deafened ex-servicemen. (W. I. Daggett and G. Chubb) 508-519. Rehabilitation of deafened service personnel. (E. D. D. Dickson) 520-525

## 61 : October 1946

- The nature of the vestibular stimulus. (L. B. W. Jongkees & J. J. Groen) 529-541  
 Headache and sinus disease: an historical survey. (D. B. Kelly) 542-551  
 A branchial cleft appearing as a post-tonsillar abscess. (W. S. Adams) 552-553  
 Royal Society of Medicine—Section of Laryngology with Section of Otolaryngology. The application of electromyography to affections of the facial and the intrinsic laryngeal muscles. (B. Feinstein) 554-558

## Journal of Mental Science

## 93 : April 1947

- Psychiatric aspects of the post-encephalitic syndrome. (D. S. Fairweather) 201-254  
 Continuous narcosis: the advantages of oral somnifaine—a comparison. (J. Walsh) 255-261  
 Types of nervous system in man, their heredity and evolution. (S. Davidenkov) 262-272  
 Moral deficiency. (L. S. Penrose) 273-277  
 A survey of subnormal types. (D. C. Jones) 278-288  
 High grade mental deficiency in relation to differential fertility. (J. A. F. Roberts) 289-302  
 Head injuries: a new treatment for the post-concussive syndrome. (H. S. E. Murray & H. Halstead) 303-317  
 Asymmetries of sensory functions (spatial and temporary discrimination) in normal persons. (H. H. Fleischhacker) 318-332  
 Contra-indications for leucotomy: whom not to leucotomize. (E. L. Hutton) 333-341  
 Brief retrograde amnesia. (G. de M. Rndolph) 342-353  
 Clinical problems of repatriates. (T. F. Main) 354-363  
 Diversional therapy at Broadmoor criminal lunatic asylum. (J. S. Knox) 364-368  
 The differential diagnosis of a conscious temporary generalized motor paralysis. (G. de M. Rndolph) 369-373  
 The psychiatric social worker in the community. (E. M. Goldberg) 374-391  
 Neurosis and religious affiliation. (E. Slater) 392-396  
 A clinical note on a rapid method of diagnosing bacillary dysentery. (A. W. Pettit) 397-398  
 Male urethral smears in mental disorders. (A preliminary communication.) (R. S. Hodge, Y. M. L. Golla, H. M. Jackson & O. George) 399-400  
 Obituary. Joseph Shaw Bolton. (J. L. Russell) 481-482

## 93 : July 1947

- The effects of intravenous insulin in Sakel's hypoglycaemic treatment. (A. M. Spencer) 483-521  
 The psycho-somatic sexual life of the family: a psycho-somatic study of suckling and coitus. (C. E. H. Turner) 522-547  
 A study of mental derangement in Africans and an attempt to explain its peculiarities, more especially in relation to the African attitude to life. (J. C. Carothers) 548-597  
 A clinical and psychological study of echo-reactions. (E. Stengel) 598-612  
 Emotional interplay and dominant personalities in therapeutic groups: observations on combined schizophrenic-neurotic groups. (F. Kraupl) 613-630  
 Observations on some cases of exhibitionism. (F. H. Taylor) 631-633  
 Obsessional states in epileptics. (G. Garmany) 639-643  
 Leptazol therapy in mental disorders: a modification using sodium amytal. (P. M. Tow) 644-649

## Journal of Neurology, Neurosurgery and Psychiatry

## 10 : February 1947

- Use of mental tests for the measurement of disability after head injury with a comparison between the results of these tests in patients after head injuries and psychoneurotics. (G. Tooth) 1-11  
 Etat marbré of the corpus striatum following birth injury. (R. M. Norman) 12-25  
 "Pins and needles": observations on some of the sensations aroused in a limb by the application of pressure. (G. Weddell & D. C. Sinclair) 26-46

## 10 : May 1947

- A mid-brain syndrome following head injury. (M. Kremer, W. R. Russell & G. E. Smyth) 49-60  
 A clinico-pathological report on unusual cases of chronic encephalitis. (W. R. Rosanoff) 61-71  
 Sensory disturbances occurring in sciatica due to intervertebral disc protrusions: some observations on the fifth lumbar and first sacral dermatomes. (M. A. Falconer, G. L. Glasgow & D. S. Cole) 72-84  
 An outbreak of atropine poisoning. (D. N. Parfitt) 85-88  
 The effect of reinnervation on collagen formation in degenerating sciatic nerves of rabbits. (M. Abercrombie & M. L. Johnson) 89-92

## Journal of Obstetrics and Gynaecology of the British Empire

## 54 : June 1947

- The relation between the results of ABO and Rh tests and the clinical condition of 2,000 mothers and infants. (K. E. Boorman, D. Daley & B. E. Dodd) 281-299  
 Studies in prematurity, stillbirth and neonatal death. Part I. Factors affecting birth-weight and outcome. (C. M. Driffield) 300-323  
 The influence of semen on the female reproductive organs. (V. B. Green-Armytage, F. Silberstein & G. E. Wachtel) 324-339

- The Rh factor in obstetrics. (A. Sadowsky, A. Brzezinski & Z. Polishuk) 340-344  
 The cause of polar lie. (F. Stabler) 345-350  
 Central rupture of the perineum. A report of a case with a review of the literature. (J. Barnes) 351-357  
 Rupture of the rectus abdominis muscle during pregnancy. (G. S. Adam) 358-362  
 An uncommon sequel of secondary rupture of the uterus. (W. F. Flint) 363-365  
 The effect of oestrogen (stilboestrol) on the formed elements of the blood in women. (K. J. Karuak) 366-368  
 The familial incidence of adrenal hypertrophy and female pseudohermaphroditism. (R. Biggs & E. Rose) 369-374  
 A fatal case of primary diphtheria of the cervix and urethra. (J. Bottomley & D. R. Christie) 375-376  
 Haematometra caused by disappearance of the cervical canal after labour. (H. S. Allen) 377-379  
 Foetal brain tumour as a cause of dystocia. (J. Baxter) 380-381  
 A case of serous adenofibroma of the ovary. (A. Sharman & A. M. Sutherland) 382-383

## Journal of Pathology and Bacteriology

## 59 : January-April 1947

- The induction of liver tumours by 4-aminoazobenzene and its N:N-dimethyl derivative in rats on a restricted diet. (A. H. M. Kirby & P. R. Peacock) 1-16  
 The carcinogenic action of 2-acetyl-amino-fluorene on various strains of mice. (E. C. Armstrong & G. M. Bonser) 19-27  
 Atypical amyloidosis in a case of plasma-cell myelomatosis. (J. H. Fodden) 29-35  
 On the use of tissue-free media for the preparation of blackquarter vaccine: (I) cysteine hydrochloride broth; (II) acid digest of liver and meat. (V. R. Rajagopalan) 37-50  
 The behaviour of *Salmonella typhi* in the agglutination reaction. (W. Hayes) 51-68  
 Staphylococcal haemolysins on sheep-blood agar with evidence for a fourth haemolysin. (R. E. O. Williams & G. J. Harper) 69-78  
 The effects of temporary occlusion of the renal artery in rabbits and its relationship to traumatic uraemia. (A. W. Badenoch & E. M. Darmady) 79-94  
 The activation of haemagglutinins by human serum. (K. E. Boorman & B. E. Dodd) 95-104  
 On certain properties of antisera prepared against human serum and its various protein fractions: their use in the detection of sensitisation of human red cells with "incomplete" Rh antibody, and on the nature of this antibody. (R. R. A. Coombs & A. E. Mourant) 105-111  
 Penicillin and *B. anthracis*. (J. M. Barnes) 113-125  
 Effect of shock-producing substances on experimental anthrax infection in mice. (J. W. Howie & J. Cruickshank) 127-135  
 Carcinoma of the pituitary gland with metastases to the liver in a case of Cushing's syndrome. (W. Forbes) 137-144  
 Haemolytic activity of *C. diphtheriae*. (L. F. Hewitt) 145-157  
 The effect of asbestos on tissue cultures: a comparative study with quartz and coal dust. (T. H. Belt, I. Friedmann & E. J. King) 159-164  
 The immunological aspects of experimental *Haemophilus pertussis* infection. (H. Proom) 165-180  
 A case of idiopathic methaemoglobinemia treated by ascorbic acid and methylene blue. (E. J. King, J. C. White & M. Gilchrist) 181-183  
 The isolation and cultivation of variola virus on the chorio-allantois of chick embryos. (A. W. Downie & K. R. Dumbell) 189-198  
 Normal and abnormal blood-counts on the Witwatersrand. (G. W. H. Schepers) 199-208  
 Catarrh of the upper respiratory tract in mice and its association with pleuropneumonia-like organisms. (D. G. ff. Edward) 209-221  
 The cytoplasmic basophilia of bone-marrow cells. (J. C. White) 223-234  
 The influence of virulence on the immunising potency for mice of *Haemophilus pertussis*, phase I. (D. F. Gray) 235-246  
 The sensitivity of organisms of the genus *Legionella* to penicillin and streptomycin. (J. A. H. Wylie & E. Vincent) 247-254  
 Some characters of coagulation necrosis due to mustard gas. (B. D. Pullinger) 255-259  
 Adaptations of the Macfarlane lecithin-vitellin test. (C. R. Owen, J. L. Langohr & E. Blakely) 261-266  
 Adrenal tumours and pseudo-hermaphroditism: a hormone study of cases. (A. M. Hain) 267-292  
 Liesegang rings and antiseptics. (R. J. V. Pulvertaft, J. R. Greening & J. A. Haynes) 293-299  
 The effect of temperature on immunity in amphibia. (K. A. Bisset) 301-306  
 Influence of oestrone on the lymphoid tissues of male mice. (L. Dmochowski & E. S. Horning) 307-312  
*Bacteroides funduliformis* (*Fusiformis necrophorus*). (A. C. Ruys) 313-316  
 Non-mannitol-fermenting *Shigella flexneri*, type 103. (M. G. Nelson) 316-318  
 A non-gas-producing strain of *B. proteus*. (A. Isaacs) 318-319  
 Two cases of adenofibroma of the epididymis. (B. Falconer) 320-321  
 Tubular adenoma of the testis and oestrogenic activity. (R. E. Rewell) 321-324  
 Tissue reaction to sericite and shale dusts treated with hydrochloric acid: an experimental investigation on the lungs of rats. (E. J. King, M. Gilchrist & M. V. Rae) 324-327  
 A case of aneurysm of the vein of Galen. (C. E. Lumsden) 328-331  
 A case of chloroma infiltrating the spinal meninges. (O. L. Wade) 331-334  
 A method for combined positive and negative staining of bacteria. (P. B. White) 334-335  
 An improved method of staining leucocyte granules with Sudan black B. (H. L. Sheehan & G. W. Storey) 336-337  
 A method for staining grossly fatty tissues with Scharlach R. (A. E. Clark) 337-338  
 An unusual congenital cardiac defect: failure of appearance of the endocardial cushions, the aortic septum and the distal part of the left sixth branchial arch. (R. E. Rewell) 339-341  
 The failure of whooping-cough and adult sera to neutralise *pertussis* toxin. (D. G. Evans) 341-342

## Journal of Physiology

## 106 : June 1947

- An experimental analysis of the jugular pulse in man. (I. F. S. Mackay) 113-118  
 The optimum intrapulmonary pressure in underwater respiration. (W. D. M. Paton & A. Sand) 119-133

The electrical activity of isolated mammalian intestines. (N. Ambache) 139-153  
 The distribution of nucleotide, phosphocreatine and glycogen in the heart. (F. Davies, E. T. B. Francis & H. B. Stoner) 154-166  
 Studies on the effect of L-tyrosine on the white rat. (W. Schweizer) 167-176  
 Rigor mortis and adenosinetriphosphate. (E. C. Bate-Smith & J. R. Bendall) 177-185  
 The effect of seat position on the efficiency of bicycle pedalling. (P. Hugh-Jones) 186-193  
 The effects of changes in dietary protein on the composition and structure of the liver cell. (H. W. Kosterlitz) 194-210  
 Effects of intrathecal injection of KCl and other solutions in cats. Excitatory action of K ions on posterior nerve root fibres. (I. Calma & S. Wright) 211-235

### 106 : July 1947

Creatinine losses in the sweat during work in hot humid environments. (W. S. S. Ladell) 237-244  
 The response of newborn rats to administration of water by the stomach. (H. Heller) 245-255  
 The response of adult and suckling rats to the administration of water and of hypertonic solutions of urea and salt. (R. A. McCance & E. Wilkinson) 256-263  
 The action of acetylcholine in the supraoptic nucleus of the chloralosed dog. (M. Pickford) 264-270  
 Reflex vasodilatation in human skeletal muscle in response to heating the body. (H. Barcroft, W. M. Bonnar & O. G. Edholm) 271-278  
 The survival of transplanted embryo bone grafted to chorio-allantoic membrane, and subsequent osteogenesis. (N. M. Hancox) 279-285  
 The mechanical and structural properties of bone in rats on a rachitogenic diet. (G. H. Bell, J. W. Chambers & I. M. Dawson) 286-300  
 The normal visual (rod) field of the dark-adapted eye. (I. Mann & F. W. Sharpley) 301-304  
 The membrane resistance of a non-medullated nerve fibre. (A. L. Hodgkin) 305-318  
 The effect of potassium on the surface membrane of an isolated axon. (A. L. Hodgkin) 319-340  
 Potassium leakage from an active nerve fibre. (A. L. Hodgkin & A. F. Huxley) 341-367  
 The effect of change of brightness level upon the foveal luminosity curve measured with small fields. (L. C. Thomson) 368-377

### Journal of the Royal Army Medical Corps

#### 88 : April 1947

An outline of the role of the medical services in the second (British) army's campaign in north-west Europe (1944-45). Part III. (R. G. Evans) 129-140  
 Medical research in the Canadian army. (W. H. Brown) 141-152

#### 88 : May 1947

An outline of the role of the medical services in the second (British) army's campaign in north-west Europe (1944-45). Part IV. (R. G. Evans) 165-185  
 A psychiatrist's observations in the B.L.A. (R. F. Fidler) 186-191

#### 88 : June 1947

The initial surgery of limb injuries. (G. H. Wooler) 205-226  
 Meningitis with multiple pyoarthritis (meningococcal). (W. C. Templeton) 227-230  
 The English army surgeon in the sixteenth century. (D. Stewart) 231-247

### Journal of the Royal Institute of Public Health and Hygiene

#### 10 : June 1947

Some possibilities in the prevention of disorders of the skin. (B. Russell) 191-205

#### 10 : July 1947

The study of epidemic influenza. (C. H. Stuart-Harris) 222-234  
 The citizen in health and sickness—some impacts of administration. (W. Elliot) 236-243

#### 10 : August 1947

Common industrial diseases and their treatment. (J. N. Agate) 257-265  
 Health inspection of imported foodstuffs—past and present. (M. T. Morgan) 266-271

#### 10 : September 1947

The Bengué Memorial Award Lecture, 1947 : a review of modern anaesthesia. (I. W. Magill) 291-299  
 Health at home and abroad. (Summaries of Public Health Reports) 300-309

### Journal of the Royal Naval Medical Service

#### 33 : January 1947

Congenital inguinal hernia in service recruits. (P. Martin & J. G. Maguire) 1-5  
 The carrier rate of intestinal infections in Trincomalee. (G. T. Stewart) 6-8  
 Systolic murmurs in healthy hearts : based on a study of 1,000 naval recruits (P. J. O'Meara) 8-16  
 D.D.T. (E. J. Mockler) 17-24  
 The hazards of toxic gases in warships excluding agents of chemical warfare. (F. P. Ellis) 25-37

### Journal of Tropical Medicine and Hygiene

#### 50 : June 1947

Hepatic bilharziasis. (M. Erfan) 104-109  
 Anaemia with dyspepsia : a syndrome encountered in Indian troops. (T. H. Howell) 110-112  
 Preliminary studies in nutritional deficiencies. (G. T. Barnes) 112-119

### 50 : July 1947

Post-war health in South-East Asia, and its importance. (H. R. O'Brien) 126-131  
 A short procedure for the isolation and preliminary identification of shigellae and salmonellae from stools. (O. Felsenfeld & V. M. Young) 131-134  
 The serum-formalin reaction in *Trypanosoma rhodesiense* sleeping sickness. (L. O. C. Cookson) 134-140

### 50 : August 1947

Induced and war malaria. (R. O. Höring) 150-159  
 Natural malaria infection in *Anopheles rufipes* (Gough). (H. M. Gelfand) 159-160  
 Notes on schistosomiasis from South Africa. (F. G. Cawston) 160-161

### Lancet

#### 1 : 7/6/47

Social aspects of epilepsy. (J. T. Fox) 775-778  
 Infective jaundice in Iceland. (L. S. Anderson) 778-781  
 Pre- and post-natal development of immunity : serum-albumin and serum-globulin levels in maternal and cord bloods of premature infants. (C. Rimington & J. A. Bickford) 781-785  
 Hypoglycaemia due to islet-cell adenoma of pancreas cured by operation. (R. L. Bishton & J. M. Malins) 785-787  
 Blood-urea in the first nine days of life. (R. A. McCance & E. M. Widdowson) 787-788  
 Postvaccinal encephalitis : two probable cases in African children. (J. N. P. Davies) 788-789  
 Diseases of the thyroid gland in occupied Belgium. (P. A. Bastenie) 789-791  
 Gummer of the thyroid. (A. H. Barber) 791  
 Modern care of old people. II. Living in a small group : Hill Homes, Highgate. 800-802

#### 1 : 14/6/47

The clinician and the Rb factor. (L. Parsons) 815-820  
 Clinical trial of di-insulin. (A. Slessor & T. Nicol) 820-823  
 Typing of typhoid bacilli with Vi bacteriophage : suggestions for its standardisation. (J. Craigie & A. Felix) 823-827  
 Folic acid in agranulocytosis. (D. A. K. Black & S. W. Stanbury) 827-828  
 Traumatic neuritis of the deep palmar branch of the ulnar nerve. (W. R. Russell & C. W. M. Whitty) 828-829  
 A case of hiccup : revival of an old remedy. (R. C. Nairn) 829-830  
 Modern care of old people. III. A contrast in methods : Orsett—Gloucestershire Hospitals. 840-842

#### 1 : 21/6/47

Infection of wounds with gram-negative organisms. Clinical manifestations and treatment. (M. E. Florey, R. W. N. L. Ross & E. C. Turton) 855-861  
 Dietetic deficiency syndromes in Indian soldiers. (J. H. Walters) 861-865  
 A typical pneumonia. Significance of cold agglutinins. (G. E. O. Williams) 865-867  
 Intradermal reaction in trichomonas infection. (S. Adler & A. Sadowsky) 867-868  
 Urticarial reactions to intramuscular penicillin. A report of four cases. (L. Steingold) 868-869  
 Post-traumatic fistula of pancreas successfully treated by surgery. (G. Flavell) 869-871  
 Bilateral pneumothorax after partial thyroidectomy. (B. R. Billimoria) 871  
 Modern care of old people. IV. A city's problems. 879-881  
 Hospital records : a plea for reform. (H. Cotton) 881-883

#### 1 : 28/6/47

Progress and present aspects of medical science. (L. Whitby) 895-899  
 Nitrogen mustards in Hodgkin's disease : report on 21 cases and 4 of other reticulosos. (M. I. R. ApThomas & H. Cullumbine) 899-901  
 Glycosuria in recruits. Incidence and classification. (J. A. Keeping & R. D. Lawrence) 901-903  
 Laboratory . . . . . oebiasis. (K. R. Hill) 903-906  
 Intrapleural . . . . . artificial-pneumothorax refills. (A. K. Miller) 906-909  
 Penicillin in surgical treatment of pasteurilla sinusitis. (E. O. Bartley & K. Hunter) 908-909  
 Survival of a baby weighing 24 oz. at birth. (J. P. Bush) 909-910  
 Plasmacytoma of pancreas and duodenum causing acute intestinal obstruction. (A. Heffernan) 910  
 Modern care of old people. V. Independent dwellings. 921-922

#### 2 : 5/7/47

Quarantine, incubation, and isolation at school. (R. E. Smith) 1-5  
 Further observations on an inhibitory substance (nisin) from lactic streptococci. (A. T. R. Mattick & A. Hirsch) 5-8  
 Effect of penicillin on serology of late and latent syphilis : a study of 120 cases followed for six months or more. (R. R. Willcox) 8-10  
 Micrognathia : report of two cases. (A. M. Sweet & M. Kemsley) 10-12  
 Management of a permanent colostomy : study of 100 patients at home. (C. E. Dukes) 12-14  
 Bronchomediastinal tuberculosis : prognosis and treatment. (H. Stevens) 14-17  
 Cerebral amoebiasis treated with emetine. (P. Collard & D. Kendall) 17-18  
 Modern care of old people. VI. Municipal institutions : Birmingham's example. 30-31

#### 2 : 12/7/47

The Centaurs or science and rulers. (W. Elliot) 41-44  
 Vagotomy for peptic ulcer. (V. C. Thompson & A. H. James) 44-47  
 Treatment of the bladder after suprapubic cystostomy. (P. W. Nathan) 47-49  
 Intravenous administration of iron. (J. A. Nissim) 49-51  
 Electro-encephalographic changes in migraine. Review of 51 cases. (D. J. Dow & C. W. M. Whitty) 52-54  
 Technique of laryngeal anaesthesia. (R. R. Macintosh) 54-55  
 The operation for congenital coarctation of the aorta : a patient's experience (H. T. van Diggelen) (64-65)  
 Modern care of old people. VII. Research at St. John's Hospital, Battersea 66-67

2 : 19/7/47

- The education of psychiatrists. (A. Lewis) 79-84  
 Vaginal resection in the treatment of duodenal ulcer. (I. M. Orr & H. D. Johnson) 84-88  
 Clinical thermometers as a possible source of cross-infection in hospital. (J. B. M. Green & J. B. Penfold) 89-90  
 Hormonal treatment of deficient lactation: results with crude anterior-pituitary extract. (M. Robinson) 90-92  
 A swallowed pin retained in the appendix. (J. Schofield) 92  
 Modern care of old people. VIII. Integrated services at Aberdeen. 106-107  
 Collection and disposal of London's refuse. (M. Sorsby) 112-113

2 : 26/7/47

- Carcinoma of the lung. Review based on 122 cases treated by pneumonectomy. (T. H. Sellors, G. Cruikshank & B. R. Billimoria) 119-121  
 Bacteriology of the collection and preservation of human milk. (J. Wright) 121-124  
 Emotional aspects of skin disease. (G. G. Robertson) 124-127  
 Effect of mass of inoculum on virulence of bacteria injected intraperitoneally in mice. (J. M. Barnes) 127-128  
 Folic acid in megaloblastic anaemia after total gastrectomy. Report of a case. (M. E. Morgans, C. Rimington & N. Whitaker) 128  
 Failures in cortical bone-grafting. (V. H. Ellis, H. H. Langston & J. S. Ellis) 128-130  
 Anti-N and other low-temperature agglutinins in human serum. (E. N. Allott & C. A. Holman) 130-131  
 Hepatic dysfunction in peptic ulcer: observations with the hippuric-acid test. (H. Pollak) 131-134  
 Staphylococcal osteomyelitis of spine in a baby aged three weeks. (P. G. Finch) 134-135

2 : 2/8/47

- Penicillin in the prevention of infection during operations on the brain and spinal cord. (J. B. Pennybacker, M. Taylor & H. Cairns) 159-162  
 The cause of postoperative shock. (A. R. Hunter) 162-164  
*H. influenzae* meningitis in infants treated with penicillin and sulphonamides. (B. Gottlieb & C. C. Forsyth) With a note on bacteriology. (E. N. Allott) 164-166  
*H. influenzae* meningitis with recovery. Report of a case. (J. Gerrard) 167-168  
 Granular proctitis treated with succinyl-sulphathiazole suppositories. (E. H. Cluer) 168-170  
 Pyrexia with hypernephroma. Report of two cases. (C. H. Catlin, E. W. Bintliffe & F. G. Marson) 170-171  
 Micro-estimation of non-protein nitrogen in serum, plasma or blood. (F. Rappaport & F. Eichhorn) 171-172  
 Treatment of prostatic cancer with  $\alpha$ -bromo- $\alpha,\beta,\beta$ -triphenylethylene (Y59). (M. Berger & N. P. Buu-Hoi) 172-173

2 : 9/8/47

- Subacute and chronic hepatitis. (A. R. Kelsall, A. Stewart & L. J. Wits) 195-198  
 Electrocortical: a new treatment of schizophrenia. (A. S. Paterson & W. L. Milligan) 198-201  
 Determination of haemoglobin. I. Determination by a cyan-haematin method. (E. J. King & M. Gilchrist) 201-205  
 Mepacrine eruptions: a case in the British Isles. (B. Russell) 205-206  
 Massive doses of adrenaline in acute toxic peripheral circulatory collapse. (C. C. Christie, T. M. Bowden, I. R. Mackenzie, J. Naismith & J. Bryant) 206-207  
 Induction of bronchogenic carcinomas in mice. (E. S. Horning) 207-209  
 The care of burned people: a plea for a new policy. (L. Colebrook) 217

2 : 16/8/47

- Cramp and salt balance in ordinary life. (A. J. Hall) 231-233  
 Human-milk bank in a maternity hospital. (J. Wright & E. M. C. Edwards) 233-234  
 Benign pneumonia in West African soldiers. (A. S. Hollins) 235-238  
 Rebleeding of children with infantile cerebral palsy. (E. Collis) 239-243  
 Congenital atresia of the oesophagus. Two cases successfully treated by anastomosis. (R. H. Franklin) 243-244  
 Sudden death from perforated gastric ulcer. (S. Silverman) 245  
 Children in day-nurseries. (B. R. Nisbet) 253  
 An outbreak of staphylococcal food-poisoning. (J. M. Ritchie, D. L. Murray & M. Holgate) 256-257

2 : 23/8/47

- Infective endarteritis of the pulmonary artery. (A. R. Gilchrist & W. Mercer) 267-272  
 Low back pain. (J. D. Paulett) 272-276  
 Fatal case of Stevens-Johnson syndrome. (D. F. Johnstone) 276-277  
 Wernicke's encephalopathy in surgical practice: report of three cases. H. J. Barrie) 278-279  
 Perinephric abscess treated with sulphadiazine and penicillin. (J. Shafar & J. Garber) 279-280  
 Myoma of the small intestine causing intestinal obstruction. (C. C. Cookson) 280  
 "Meadone": an analgesic drug. (A. J. H. Hewer & C. A. Keele) 281  
 Nitrogen trichloride and canine hysteria. (T. Moran) 289-291  
 Working conditions in iron foundries: advisory committee's report. 292

2 : 30/8/47

- The doctor's mission. (J. R. Learmonth) 303-304  
 Two essays on the practice of medicine. (R. Platt) 305-307  
 Social medical teaching. (W. M. Arnott, T. McKeown & F. A. R. Stammers) 307-308

2 : 6/9/47

- Coalminers. (J. N. Morris) 341-346  
 Penicillin as an aid in prostatectomy. (J. G. Y. Bell) 347-350  
 Liver and folic acid in the treatment of nutritional macrocytic anaemia: a comparison of results. (T. A. Kemp) 350-353  
 Acute anterior poliomyelitis complicating pregnancy. (D. M. W. Maxwell & P. H. Willcox) 353-355  
 Acute amoebiasis complicating cholecystectomy: report of a case. (K. M. Robertson) 355-356

2 : 13/9/47

- Gastrectomy: a human experiment. (H. Ogilvie) 377-379  
 Congenital hypoproteinaemia and pseudo-hypoproteinaemia. (A. J. Quick) 379-382  
 Denatured calf plasma for transfusion. (J. Melka, V. Rapant & B. Zapletal) 382-383  
 Anthrax in the management of liver and insulin sensitivity. (R. B. Hunter & A. G. S. Hill) 383-385  
 Hormones and lactation. Dried thyroid gland. (M. Robinson) 385-387  
 Haemoglobinuria after intravenous myanesin. (J. L. Pugh & G. E. Enderby) 387-388  
 Urethane and stilbamidine in multiple myeloma: report on two cases. (N. Alwall) 388-389  
 Bovine cartilage in plastic surgery. (W. E. M. Wardill & J. Swinney) 389-390  
 Recruitment and training of nurses. The working party's report. 401-403  
 Food consumption in the United Kingdom. Official figures. 403-404

2 : 20/9/47

- The future of preventive inoculations. (H. J. Parish) 413-417  
 Meningitis leptospirosis. (E. M. Buzzard & J. A. H. Wylie) 417-420  
 Dicoumarol poisoning with relapse: report of a case. (G. Thorsén) 420-422  
 Intravaginal implantation of hormone pellets. (B. Zondek) 423-424  
 Internal pneumonolysis: results in 393 cases. (F. L. Wollaston) 424-425  
 Adrenalectomy and prostatic carcinoma: report of three cases. (H. T. Cox) 425-426  
 International Conference of Physicians. Scientific discussions. 434-441

2 : 27/9/47

- Ganglia in the communicating rami of the cervical sympathetic trunk. (T. Skoog) 457-460  
 Nutritional value of diets eaten by old people in London. (M. Pike, R. Harrison, S. Holmes & K. Chamberlain) 461-464  
 The walking calliper. (J. Charnley) 464-467  
 Irregular response to liver extract in pernicious anaemia. (J. F. Wilkinson & M. C. G. Israëls) 468-469  
 Treatment of acute appendicitis. (T. Gray) 469-470

## Medical Officer

77 : 7/6/47

- Staff absenteeism with special reference to day nurseries. (A. Anderson) 229-231

77 : 14/6/47

- The R.S.I. Health Congress at Torquay. Inaugural address. (Fortesque). What of the future? (A. Davidson). The end of an epoch. (W. A. Daley) Health visitors and the N.H.S. Act. (D. M. Taylor) 239-243

77 : 21/6/47

- The R.S.I. Health Congress at Torquay. The N.H.S. Act, 1946, and the public health service. (E. K. Macdonald). Rural hygiene in the tropics. (G. Macdonald) 251-253

77 : 28/6/47

- The R.S.I. Health Congress at Torquay. Education for health. (F. A. E. Crew). Divisional county administration under the N.H.S. Act, 1946. (W. G. Patterson) Infantile mortality. (C. McNeil) 261-265

78 : 5/7/47

- The Society of Medical Officers of Health. 5-7

78 : 12/7/47

- The Association of Sea and Air Port Health Authorities of the British Isles. 15-16

78 : 19/7/47

- Care of the aged. (C. O. S. B. Brooke) 27-28  
 Are we making the best use of Health Visiting Staff? (B. M. Langton) 28-31

78 : 26/7/47

- The hygiene services of the Army. (H. D. Chalke) 37-38

78 : 2/8/47

- Tuberculosis and the war. (B. W. Anderson) 47-49  
 The medical inspection of aliens. (V. O. B. Gartside) 49-50  
 Medical examinations at the University of Montreal. (J. N. Laporte) 50

78 : 9/8/47

- Causes of increase in stillbirths and infantile deaths. (P. H. J. Turton) 57-58  
 Problems of public health administration. (I. A. G. MacQueen) 59-60

78 : 16/8/47

- Qoo vadis? (A. Walker) 69-71  
 The control of venereal disease in the expectant mother. (N. Wattie) 71-73

78 : 23/8/47

- Housing conditions in a rural district. (W. B. Stott) 81-82  
 Anterior poliomyelitis. (V. O. B. Gartside) 82-84

78 : 30/8/47

- A study of ante-natal records. (J. V. Walker) 91-92  
 32 years at Leeds: a valedictory address. (J. J. Jervis) 92-94

78 : 6/9/47

- Epidemic of enteric group fever: city of Prato (June, 1944—February, 1945). (G. C. Taylor) 101-103  
 Food education. (P. H. J. Turton) 104  
 Population trends. (C. Rolleston) 104

78 : 13/9/47

- The future of the chronic sick. (T. H. Howell) 113  
 The problem of the spastic child. [Memorandum from the British Council for the Welfare of Spastics.] 113-114

78 : 20/9/47

- B.C.G. vaccination. (J. G. Cairns) 123  
 A mediaeval poet (Lydgate) on health. (E. D. Irvine) 123-124  
 Public health services in the United States. (W. P. Shephard & R. M. Atwater) 125-126  
 Ministry of Health return of infectious diseases. 128

78 : 27/9/47

- The Public Health Service as a career. (F. Hall) 133-134  
 Ministry of Health return of infectious diseases. 139

## Medical Press

217 : 4/6/47

- The importance of diet in skin diseases. (G. W. Bamber) 472-474  
 The value of gastroscopy. (J. D. Rose) 474-479  
 Prefrontal leucotomy. (R. E. Hemphill) 480-482  
 The treatment of pyelitis in children. (G. H. Newns) 483-485

217 : 11/6/47

- The clinical application of amino-acid therapy. (J. H. Hannan) 497-501  
 The early clinical diagnosis of common hip-diseases in children. (H. G. Korvin) 502-505  
 Regional analgesia. (V. Goldman) 505-508  
 Schistosomiasis. (F. G. Cawston) 508-509

217 : 18/6/47

- The prevention and treatment of toxic effects of the sulphonamides. (R. W. Luxton) 517-523  
 Consanguinity and disease. (J. W. McFeeters) 523-526  
 The pre- and post-operative treatment of the peptic ulcer. (I. I. Price) 526-530

217 : 25/6/47

- The modern treatment of fractures of the carpal scaphoid. (J. R. Armstrong) 539-542  
 The diagnosis and treatment of non-venereal vaginal discharges. (R. W. Knowlton) 543-545  
 The incidence, treatment and prognosis of tuberculous laryngitis in pulmonary tuberculosis. (V. Lambert) 546-548  
 Some day-to-day problems in the infant welfare centre. (L. Munro) 548-551

218 : 2/7/47

- The modern treatment of acute haematogenous osteomyelitis. (E. C. B. Butler) 5-8  
 The investigation and treatment of haematuria. (A. E. Roche) 8-11  
 Physiotherapy in general practice. (H. Morris) 12-15  
 Medicine: art or science? (D. Guthrie) 15-21

218 : 9/7/47

- Development of medicine in industry. (J. C. Bridge) 29-30  
 The diagnosis of lead poisoning. (D. A. K. Cassells) 30-32  
 Medical care of women in industry. (M. P. Fitzsimons) 32-35  
 Skin hazards and their prevention and the treatment of industrial dermatitis. (W. C. Cresdee) 35-38  
 The organisation of the medical department. (N. G. Marr) 38-40  
 Some medical aspects of work in a metal refinery. (J. G. Morgan) 41-43  
 Visual education—3. Filmstrip in medical education. (P. Hansell) 44-47

218 : 16/7/47

- The aetiology and treatment of backache. (A. H. Baker) 57-60  
 The care of children's teeth. (F. J. Ford) 61-65  
 The physical basis of depression. (T. D. Power) 65-67

218 : 23/7/47

- Modern treatment of acute otitis media. (H. V. O'Shea) 79-82  
 Common congenital orthopaedic defects. (B. L. McFarland) 82-84  
 The value of the psychiatric out-patient clinic to the general practitioner. (J. J. O'Reilly) 85-88  
 The doctor as detective. (L. A. Parry) 88-94

218 : 30/7/47

- The management and modern treatment of the fibrillating heart. (J. W. Macfarlane) 101-103  
 The revival of England. (T. H. Sanderson-Wells & J. Jenks) 103-108  
 Injuries to the wrist. (I. D. Kitchin) 108-112  
 An alternative to present-day medicine?—A layman's point of view. (J. Yahuda) 112-117

218 : 6/8/47

- Endometriosis. (M. F. Potter) 123-125  
 Some medico-legal aspects of unintentional homicide—I. (O. C. M. Davis) 125-127  
 Urine therapy. (J. Plesch) 128-133  
 Penicillin reactions. (P. Keaney & R. Grenville-Mathers) 133-134

218 : 13/8/47

- Delayed union and non-union of fractures. (M. Albert) 141-144  
 "Dead hand" in operators using electrically-driven cutting tools. (K. Bident-Steele & F. H. King) 144-148  
 Psychology and blood pressure in certain flying personnel. (W. W. Mackinlay) 148-152  
 Medical evidence in cases where the defence is insanity—II. (O. C. M. Davis) 152-155

218 : 20/8/47

- Indications for and precautions in orthodontic treatment in children. (W. R. Logan) 163-166  
 Alginates in surgery. (G. Blaine) 166-169  
 Chronic bronchial asthma and other allergic states treated with ethylene disulphonate, under war-time conditions in Britain. (J. Bodman & E. Felix) 169-176  
 Medical evidence in cases where the defence is insanity—III. (O. C. M. Davis) 176-179

218 : 27/8/47

- Legg-Perthes' disease. (D. M. Aitken) 184-186  
 Anaesthesia for plastic and thoracic surgery. (H. R. W. Franklin) 187-196  
 Lumbago. (F. G. Cawston) 196-197  
 Medical evidence in cases where the defence is insanity—IV. (O. C. M. Davis) 197-200

218 : 3/9/47

- The social aspects of homosexuality. (E. A. Bennet) 207-210  
 Some criminological aspects of homosexuality. (H. Mannheim) 210-212  
 Sexual inversion: the problem of treatment. (D. Stanley-Jones) 212-215  
 Homosexuality. (N. East) 215-217  
 A note on the psychotherapeutic treatment of homosexuality in prison. (J. C. Mackwood) 217-219  
 Homosexuality in women. (A. L. Winner) 219-220  
 The medico-legal problem of homosexuality. (D. Stafford-Clark) 220-222  
 Homosexuality: the psychological factor. (C. Allen) 222-223

218 : 10/9/47

- The treatment of compound fractures of the femur. (B. E. Oblatz) 231-234  
 The treatment of unerupted molar teeth. (S. A. Riddett) 234-237  
 Haemolytic transfusion reactions. (J. F. Loutit) 238-241  
 Ovarian tumours. (R. L. Hartley) 241-245

218 : 17/9/47

- Vaginitis in adults: some causes, their diagnosis and treatment. (F. C. Doble) 253-256  
 The significance of vertigo and nystagmus in cases of brain tumour. (T. O. Howie) 256-260  
 Assessment of recovery rates in schizophrenia. (I. Atkin) 261-263  
 The social aspect of tuberculosis. (F. R. G. Hearf) 263-267

218 : 24/9/47

- Modern views on and treatment of phlyctenular conjunctivitis. (J. H. Daggart) 275-277  
 Post-graduate education in public health. (J. M. Mackintosh) 278-281  
 Large municipal hospitals in Ireland. (T. P. C. Kirkpatrick) 281-285  
 Education in general medicine. (J. D. Kershaw) 285-289  
 Henry VIII recalled. (W. R. Bett) 289-290

## Monthly Bulletin of the Ministry of Health and the Public Health Laboratory Service

6 : May 1947

- [There appears to be an error in the pagination of this number; cf. 6 : April 1947, of which the contents were listed in the Guide to the Journals, *BMB* 1098.]  
 Breast feeding and the early phase of lactation. (H. Waller) 73-81  
 Post war school dentistry. (A. T. Wynne) 81-88  
 Notification of infectious disease in England and Wales: March, 1947. 88  
 An extensive outbreak of infection due to *Salmonella typhimurium*. (F. E. Camps) 89-94  
 Formalin in filter paper. (A. I. Messer) 94-95

6 : June 1947

- Standards for day nurseries. (G. I. Brodie) 98-101  
 The incidence of stammering and speech defects in school children. (P. Henderson) 102-105  
 Accidents in the home. (S. G. Abelson) 105-106  
 Biting midges. (J. R. Busvine) 107-108  
 Survey of sickness prevalence. 108  
 Notification of infectious disease in England and Wales: April, 1947. 108  
 A report on the trial of a lotion applied to the skin of new-born infants as a preventive against pemphigus neonatorum. (V. D. Allison & B. C. Hobbs) 109-111  
 A fatal case of *Bact. asiaticum* infection simulating acute food poisoning. (J. C. Kerrin) 112-113

6 : July 1947

- Indigenous malaria in Great Britain. (P. G. Shute) 116-121  
 Smallpox in the first half of 1947. (W. H. Bradley) 121-123  
 Survey of sickness prevalence, 1946. 123-129  
 The use of D.D.T. emulsion for the control of cockroaches. (A. W. McKenny-Hughes) 129-130  
 Notification of infectious disease in England and Wales: May, 1947. 130  
 Local and general reactions following the injection of adults with T.A.F. and diphtheria antiserum. (T. A. Cockburn) 131-134  
 A new type of *Salmonella*: *Salmonella cambridge*. (M. M. Wilson, J. Taylor & E. S. Anderson) 135-136

6 : August 1947

- Current outlook in cerebro-spinal fever. (H. S. Banks) 138-141  
 Acute poliomyelitis. A memorandum by medical officers to the Ministry of Health. 141-144

Notifications of infectious diseases in September and December quarters of 1946, according to sex and age, and corrected for subsequent changes in diagnosis. 145-147  
 Notification of infectious disease in England and Wales: June, 1947, 147  
 Field investigation of paratyphoid fever with typing of *Salm. paratyphi B* by means of Vi bacteriophage. (P. H. Martin) 148-151

### Nutrition Abstracts and Reviews

16 : April 1947

Production and modification of liver disease by diet. (L. E. Glynn) 751-762

### Practitioner

158 : June 1947

Modern views on the causation of hypertension. (C. Wilson) 453-460  
 The surgical treatment of hypertension. (J. R. Learmonth) 461-466  
 The medical treatment of hypertension. (T. East) 467-469  
 The criteria of hypertension. (G. Bourne) 470-475  
 The prognosis in hypertension. (K. D. Wilkinson) 476-481  
 The new anti-histamine drugs in relation to the histamine theory of allergy. (D. Harley) 482-488  
 The diagnosis of dyspepsia. (T. H. Oliver) 489-493  
 Practical points in the treatment of the chronic sick. (T. H. Howell) 494-496  
 The texture of thought. (C. G. Learoyd) 497-503  
 Pain and its problems. VI.—Pain in the gastro-intestinal tract. (B. A. McSwiney & C. B. B. Downman) 506-511  
 Revision corner: The treatment of paroxysmal tachycardia. (C. J. Gavey) 512-514. The use and abuse of analgesic drugs. (E. J. Wayne) 514-516

159 : July 1947

The Rotunda Hospital: two hundred years of midwifery: the bicentenary of the Rotunda Hospital. (N. M. Falkiner) 1-10  
 Breech presentations. (A. Brews) 11-14  
 Placenta praevia. (T. N. A. Jeffcoate) 15-21  
 The rôle of radiology in obstetrics. (M. E. Grossmann) 22-28  
 The puerperium. (J. H. Peel) 29-32  
 The care of the newborn. (F. M. B. Allen) 33-39  
 The management of the new-born infant: personal experiences. 40-43  
 Heat spots and summer eruptions. (J. T. Ingram) 44-49  
 The technique of B. C. G. vaccination. (K. N. Irvine) 50-54.  
 Infections of the skin of the scalp in childhood. (A. G. Fergusson) 55-59  
 Pain and its problems. VII. Pain in the rheumatic diseases. (G. D. Kersley) 60-65  
 The centenary meeting of the American Medical Association, Atlantic City, June, 9-13, 1947. 66-69  
 Revision corner: contents of obstetric bag for use by a general practitioner. (W. C. W. Nixon) 70  
 The treatment of *Trichomonas vaginalis* infestation. (R. Lees) 71-72  
 The diagnosis of pruritis. (H. Goadby) 72-74

159 : August 1947

The use and abuse of rest. (Horder) 83-86  
 Post-operative convalescence. (H. Atkins) 87-94  
 Convalescence in childhood. (W. S. Craig) 95-100  
 Convalescence in obstetrics. (A. W. Purdie) 101-108  
 Climate and convalescence. (A. Abrahams) 109-115  
 Convalescent homes. (C. Morris & M. L. Ward) 116-121  
 Herpes zoster. (J. G. M. Hamilton) 122-127  
 The recognition of neurotic illness. (H. G. Miller) 128-135  
 Pain and its problems. VIII.—Pain in midwifery and gynaecology. (G. W. Theobald) 136-142  
 Revision corner: The treatment of epilepsy. (D. Kendall) 143-145. The choice of iron preparations. (R. R. Bomford) 145-147. The treatment of pyelitis and cystitis. (M. L. Rosenheim) 147-148.

### Proceedings of the Royal Society, B

134 : July 1947

Croonian lecture. On the structure of biological fibres and the problem of muscle. (W. T. Astbury) 303-328  
 Ferrier Lecture. Some observations on the cerebral cortex of man. (W. Penfield) 329-347  
 Antoine Laurent Lavoisier, 26 August 1743—8 May 1794. (H. Hartley) 348-377  
 The differentiation of neural crest cells into visceral cartilages and odontoblasts in *Amblystoma*, and a re-examination of the germ-layer theory. (G. R. de Beer) 377-398  
 A Swedish deep-sea expedition. (H. Pettersson) 399-407  
 Contribution to the study of the sponges. (M. W. Jepps) 408-417  
 The distribution of vitamin B<sub>1</sub> and nitrogen in the wheat grain. (J. J. C. Hinton) 418-429

### Proceedings of the Royal Society of Medicine

40 : May 1947

Nutritional liver disease in West Indian infants. (J. C. Waterlow) 347-351  
 Some renal effects of experimental dietary deficiencies. (H. Heller & S. E. Dicker) 351-353  
 Discussion on radioactive tracers. 354-360  
 Discussion on stress incontinence in micturition. 361-370  
 Discussion on the management of the normal third stage of labour and of haemorrhage therein. 370-376  
 The treatment of tuberculous salpingitis with special reference to X-ray therapy. (E. Philipp) 376-378  
 Full-term intrauterine pregnancy. (I. T. Fraser) 378-379  
 Uterine rupture. (L. Donald) 379-380

Discussion on modern methods in the control of airborne infections. 381-383  
 Whooping cough and measles: an epidemiological concurrence and contrast. (W. Butler) 384-398  
 Value of tomography in lesions of the main bronchi and their larger sub-divisions. (S. Nowell) 399-405  
 Disseminated ossified nodules in the lungs associated with mitral stenosis. (A. Elkeles) 405-408  
 Discussion on the treatment of cancer of the tongue. 409-418

40 : June 1947

Isolated oculomotor palsy caused by intracranial aneurysm. (G. Jefferson) 419-432  
 Discussion on the use of penicillin in urology. 433-442  
 Rheumatic diseases: a challenge and an opportunity. (H. Cohen) 443-452  
 Clinical science in the light of history. (A. P. Cawadiaz) 453-462

40 : July 1947

Discussion on pain in the upper limb, excluding shoulder lesions. 492-498  
 The sterilization of dental handpieces. (W. Harvey, C. H. LeMay & C. W. Shettleworth) 507-511  
 The "three-ply" structure in facial bones. (W. W. James) 511-514  
 Intrinsic cancer of the larynx. Review of a series of cases. (V. E. Negus) 515-524  
 Discussion on local analgesia. 525-532  
 Demonstration: diagnosis of threadworms. (J. M. Watson & R. C. MacKeith) 539-540  
 Discussion on anaesthesia in children. 540-544  
 Erythroblastosis foetalis or haemolytic disease of the newborn. (Abstract of illustrated talk). (L. K. Diamond) 546-550

40 : August 1947

Discussion on anaesthesia for Caesarean section. 557-568  
 Discussion on radiotherapy in the treatment of non-malignant superficial eye lesions. 570-577  
 Discussion on allergy in ophthalmology. 578-582  
 Disorders of skill: an experimental approach to some problems of neurosis. [Abstract.] (D. R. Davis) 583-584  
 Discussion on the social aspects of homosexuality. [Summary.] 585-592  
 Discussion on further experiences with eurare. 593-602  
 Controlled respiration by means of special automatic machines as used in Sweden and Denmark. [Abstract.] (E. T. Moersch) 603-607  
 Skin temperature as a clinical aid during anaesthesia. [Abridged.] (J. Clutton-Brock) 607-608

### Public Health

60 : June 1947

The Medical Officer of Health and infectious disease practice. (E. Hughes) 175-177  
 The change from school to industry: I. From the point of view of the School Health Service. (A. A. E. Newth) 177-179  
 The change from school to industry: II. From the point of view of the Industrial Medical Officer. (T. A. L. Davies) 179-183

60 : July 1947

The modern approach to venereal disease and dermatology. (A. Fessler) 197-200  
 Breast-feeding, with special reference to social factors. (E. J. Williams) 201-204  
 Health centres for Leeds. (J. F. Warin) 204-205

60 : August 1947

Ascertainment of visual defect in children: an approach to the problem with particular reference to the provision of special educational facilities. (D. D. S. Stewart) 215-219  
 Care of the aged: a review of current literature and opinion. (E. D. Irvine) 219-221

60 : September 1947

Public health problems in the A.T.S. (A. L. Winner) 232-235  
 The work of the Health Division of the UNRRA Italian Mission, 1944-47. (E. C. Benn) 235-238

### Quarterly Journal of Medicine

16 : April 1947

Oedema in an internment camp. (R. A. Pallister) 47-60  
 Mepacrine and falciparum malaria. (J. Reid) 61-82  
 A review of chronic intermittent juvenile jaundice. (E. Meulengracht) 83-93

16 : July 1947

Fat absorption in tropical sprue. (D. A. K. Black, J. P. Bound & L. P. R. Fourman) 99-109  
 Heredity in hypertension. (R. Platt) 111-133  
 The significance of the van den Bergh reaction. (C. H. Gray) 135-142  
 Hypertension and unilateral kidney disease. (G. J. Langley & R. Platt) 143-155  
 The aetiology, diagnosis, and treatment of prolapsed intervertebral disk, with a review of 300 cases of sciatica. (D. Kendall) 157-179  
 Fainting and flying. An analysis of 500 cases of impairment of consciousness in pilots and aircrew. (A. F. Rook) 181-209

### Quarterly Journal of Pharmacy and Pharmacology

20 : January-March 1947

A method for the estimation of total alkaloids in belladonna and stramonium. (M. Roberts & W. O. James) 1-16  
 A micro-gasometric method for determining small concentrations of oxygen in nitrogen-filled ampoules. (N. H. Law) 17-22  
 The comparative value of arachis oil with beeswax and ethyl oleate with beeswax in delaying absorption of penicillin. (F. M. Berger) 23-27  
 A simple biological assay of curare preparations. (F. D. Garcia de Jalón) 28-30

Observations on the pharmacology of miracil, a new chemotherapeutic agent for schistosomiasis. (D. R. Wood) 31-37  
 Investigations on Indian medicinal plants. Part I. *Asteracantha longifolia*. (N. K. Basu & S. B. Lal). *Trianthema monogyna* Linn. (N. K. Basu & S. N. Sbarma). *Boerhaavia diffusa* Linn. (N. K. Basu & S. N. Sbarma) 38-42

### 20 : April-June 1947

The pharmacological properties of iodinated choline and brominated choline. (H. Cullumbine & F. F. McDonald) 81-83  
 Betanaphthol in gelatin capsules—its use as a preservative, with a method for its determination. (S. J. Patterson & A. F. Lerrigo) 83-86  
 A polarographic study of alkaloids. Part VI. (H. F. W. Kirkpatrick) 87-94  
 The effect of anaesthetic and other substances on the paralytic action of myanesisin. (F. M. Berger) 94-99  
 On the chromatographic analysis of alkaloidal salts and on aluminium oxide for quantitative chromatographic analysis. (F. Reimers, K. R. Gottlieb & V. A. Christensen) 99-109  
 The determination of barbituric acid derivatives. (H. A. Mangouri & L. Milad) 109-113  
 Derivatives of propylbenzene as synthetic sex hormones. Part I. (K. S. Kaikini & W. H. Linnell) 113-118  
 Isonicotinamides. (W. H. Linnell & A. F. Vyas) 119-123  
 The relation between the potency of the British Standards Institution Provisional Standard Preparation of vitamin D<sub>2</sub> and that of other sources of vitamin D, with special reference to the vitamin D<sub>2</sub> potency of the U.S.P. Reference Cod Liver Oil No. 2. (H. M. Bruce, S. K. Kon, W. A. Broom & G. L. M. Harmer) 123-129  
 The synthesis of a new homologue of mescaline. (P. Hey) 129-134  
 Investigations on Indian medicinal plants. Part II. *Hydrocotyle asiatica* Linn. (N. K. Basu & P. P. Lamsal). *Vitex-negundo* Linn. (N. K. Basu & G. B. Singh). *Monniera cuneifolia*. (N. K. Basu & P. R. Pabrai) 135-139

### 20 : July-September 1947

The changing face of pharmacy. (B. A. Bull) 169-176  
 The hygroscopic capacity of commercial samples of penicillin and its effect upon their stability. (H. Brindle & W. G. Keepe) 177-182  
 Crystalline sodium penicillin G. Some observations on its stability in solution and on related matters. (B. Johnson & A. F. Lerrigo) 183-197  
 Crystalline sodium penicillin G in pharmaceutical preparations. (W. A. Woodard) 197-212  
 The use of antiseptics in the sterilisation of solutions for injection. Part I. The efficiency of chlorocresol. (G. E. Davies & J. E. Davison) 212-218  
 The analysis of papaveretum. (D. C. M. Adamson, F. P. Handiside & H. W. Hodgson) 218-227  
 The d-tubocurarine content of curare. (G. E. Foster & J. V. Turner) 228-234  
 A colorimetric method for jaborandi alkaloids. (W. F. Elvidge) 234-237  
 The determination of calomel in pills. (G. J. W. Ferrey) 237-240  
 The fluorimetric assay of aneurine; a comparison of the United States Pharmacopoeia XIII and other methods. (H. Williams & F. Wokes) 240-257  
 The adsorption of aneurine from solutions of the pure substance. (C. Daglish) 257-263  
 The analytical control of pharmaceutical preparations containing vitamins B<sub>1</sub> and B<sub>2</sub>. (W. F. Elvidge) 263-272  
 Valerian, European and Indian: volatile oil content and alcohol-soluble extractive. (T. E. Wallis & P. K. Sanyal) 272-281  
*Ammi malus* Linn.: pharmacognostical study and isolation of a crystalline constituent, ammoidin. (I. R. Fabry & H. Abu-Shady) 281-291  
 Determination of clove stalk in powdered clove. (T. E. Wallis & D. K. Santra) 291-299  
 The inactivation of enzymes and micro-organisms in oils and powders. Part I. The thermolability of lipase in powder form and in suspension in oil. (K. Bullock) 299-311  
 The inactivation of enzymes and micro-organisms in oils and powders. Part II. The effects of drying on the viability of bacteria, and their thermolability in powders. (K. Bullock & J. W. Lightbown) 312-328  
 A note on solutions of kiton green for vital staining. (T. D. Whittet) 328-331  
 The evaluation of the bactericidal activity of ethylene glycol and some of its monoalkyl ethers against *Bacterium coli*. Part I. (H. Berry & I. Michaels) 331-347  
 The evaluation of the bactericidal activity of ethylene glycol and some of its monoalkyl ethers against *Bacterium coli*. Part II. (H. Berry & I. Michaels) 348-367  
 The assay of fullers' earth for montmorillonite content. (W. Smith) 367-372  
 The determination of iodine in chbinofon and certain other iodocompounds. (A. D. Powell & E. A. Taylor) 373-376  
 The decline of pyrogenic activity of intravenous solutions during storage. (H. O. J. Collier & S. K. Paris) 376-380  
 Comparative activities of amebocaine, cinchocaine and procaine as local anaesthetics. (G. F. Somers & N. D. Edge) 380-387  
 Para-chlorophenyl- $\alpha$ -glycerol ether as an antibacterial and antifungal agent of pharmaceutical interest. (F. Hartley) 388-395  
 Variations in hand-made pills. (H. Davis & D. C. Garratt) 395-400

## Rheumatism

### 3 : July, August, September 1947

The treatment of arthritis by electrically activated vaporized ergosterol: a preliminary report. (G. Norris) 106-107  
 Observations on chronic rheumatism as a possible allergic disease. (L. J. Barford) 108-110  
 Abuse of rest in arthritis. (O. Meyer) 111-115  
 Some observations on the types of rheumatoid arthritis with special reference to one associated with sympathetic hypertonus. (L. F. A. Parr & E. Shipton) 116-118

## Thorax

### 2 : June 1947

Arteriovenous aneurysm on the pulmonary artery simulating patent ductus arteriosus Botalli. (G. Björck & C. Crafoord) 65-74  
 Diseases of the lung resulting from occupational dusts other than silica. (K. M. A. Perry) 75-120

### 2 : September 1947

Coarctation of the aorta. (C. Crafoord, B. Ejrup & H. Gladnikoff) 121-147  
 Primary carcinoma of the trachea. (P. Ellman & H. Whittaker) 153-162; plates, 151-152  
 Intra-thoracic lipomata. (J. Smart & V. C. Thompson) 163-168; plates, 148-150

## Transactions of the Royal Society of Tropical Medicine and Hygiene

### 40 : May 1947

Recent knowledge about malaria vectors in West Africa and their control. (R. C. M. Thomson) 511-536  
 The transmission of malaria in Borneo. (J. McArthur) 537-558  
 Action of gammexane on arthropods of medical and veterinary importance. (J. S. Steward) 559-565  
 Destruction of adult mosquitoes by residual DDT methods. (L. G. Eddey) 567-588  
 The residual action of DDT against *Anopheles gambiae* and *funestus*. (K. S. Hocking) 589-601  
 Experiments with DDT on various species of tsetse flies in the field and laboratory. (F. L. Vanderplank) 603-620  
 Sidelihts on malaria in man obtained by subinoculation experiments. (N. H. Fairley *et al.*) 621-676  
 Monkeys in relation to yellow fever in Bwamba County, Uganda. (A. J. Haddow, K. C. Smithburn, A. F. Mahaffy & J. C. Bugher) 677-700  
 The behaviour of a Sudan strain of *Leishmania donovani* in *Phlebotomus papatasi*. A comparison of strains of *Leishmania*. (S. Adler) 701-712  
 Mucocutaneous leishmaniasis in Kenya (with a note on penicillin treatment). (F. Piers) 713-718  
 Exoerythrocytic schizogony in *Plasmodium kochi* Laveran. A preliminary note. (P. C. C. Garnham) 719-722

### 40 : July 1947

Observations on trypanosomiasis in the Belgian Congo. (L. M. J. J. Van Hoof) 728-761  
 Intensive trypanamide therapy in the treatment of trypanosomiasis. (A. F. Fowler) 763-770  
 Hyperglycaemic action of snake venoms in relation to their toxic and antigenic properties. (E. Grasset & L. Goldstein) 771-788  
 Primary splenic abscess. (M. Gelfand) 789-793  
 Malaria in the natives of New Guinea. (N. G. Hairston, F. B. Bang & J. Maier) 795-807  
 DDT spraying inside houses as a means of malaria control in New Guinea. (F. B. Bang, N. G. Hairston, J. Maier & F. H. S. Roberts) 809-822  
 DDT aerosol in malaria control in East Africa. (D. B. Wilson & A. G. Robertson) 823-850  
 Dengue in Iraq. (R. F. Fleming & J. M. French) 851-860  
 Jungle yellow fever in Surinam. (E. P. Snijders, M. F. Polak & J. Hoekstra) 861-868  
 Studies in leishmaniasis in the Anglo-Egyptian Sudan. IX. Further observations on the sandflies (*Phlebotomus*) of the Sudan. (R. Kirk & D. J. Lewis) 869-888  
 Canine visceral leishmaniasis in villages west of Lancow, China. (E. A. Ho, T. -H. Hsu & T. -H. Soong) 889-894  
*Leptospira icterohaemorrhagiae* in rats of Beirut. (B. H. Kalfayan) 895-900  
 The survival of transfused erythrocytes in sickle-cell anaemia. (A. Altman) 901-904

## Introduction

There has recently been published an account of the six public lectures delivered to the XI International Congress of Pure and Applied Chemistry which was held in London last year. From this account it is seen that four of the six lectures were clearly of biochemical substance, while the fifth, that delivered to the section of Organic Chemistry, was largely devoted to natural materials of the liveliest concern to biochemists. Since the Congress was concerned with chemistry in the widest sense of the word, the devotion of such a large proportion of interest to matters of biological import once again emphasizes the immense influence which biochemistry is exerting upon the primary sciences.

It is good that the emphasis on the "chemistry" in "biochemistry" should be sounded, but such an emphasis carries with it two potential dangers. First, the attractiveness of those investigations which are devoted to the chemistry of substances of biological significance may detract seriously from the fundamental work on chemistry for its own sake, work upon which future developments inevitably rest. For example, progress in the development of methods for the synthesis of penicillin are impeded by the paucity of fundamental knowledge concerning the chemistry of four-membered rings containing a nitrogen atom. It is of the greatest importance to biochemistry and to medicine that chemists should never cease to explore the

reactions and properties of purely synthetic substances, even though such substances have apparently no connexion with biology or with medicine.

The second danger is more subtle but nevertheless just as real. It is of the highest importance that the spectacular results which have already been achieved by a purely chemical attack upon biological materials should not divert the attention of biochemists from the core of the problem of biochemistry—the study of the enzyme system within the cell. Although chemistry and biochemistry must necessarily overlap to a substantial extent, the chemist is primarily interested in the fragmentation and synthesis of molecules in the laboratory, while the biochemist should be, and is, more fundamentally concerned with the changes which substances undergo within a living system, both in the building up of such a system, and in the maintenance of it by metabolic processes.

In this country the dynamic approach to biochemical problems was largely founded by the investigations and ideas of the late Sir Frederick Gowland Hopkins, whose famous dictum, "Life is the expression of a particular dynamic equilibrium which obtains in a polyphasic system", is quoted in the article, *Biochemical Integration in Cellular Function*, by Dr. Ernest Baldwin, a pupil of Gowland Hopkins, which appears in the present issue. It is therefore not inappropriate that this issue of the *British Medical Bulletin* should be regarded as a tribute to the work and memory of Sir Frederick Gowland Hopkins. The article on Gowland Hopkins by Joseph and Dorothy Needham has been written from a personal point of view which, it may be hoped, will assist many who did not know Hopkins to appreciate something of the charm and inspiration which he shed upon those around him. It is fitting, too, that the ideas and teaching of Hopkins and his school should recently have been ably summarized in a textbook by Ernest Baldwin entitled *Dynamic aspects of biochemistry* (Cambridge University Press, 1947), a book which will almost certainly inspire the teaching of the subject for many years to come.

It is one of the triumphs of biochemistry that it provides a potent integrating force in medicine which, until the present time, had been completely lacking. For instance, the integration of such diverse branches of medicine as bacteriology and nutrition on a biochemical

basis is now so widely accepted that the articles on *Metabolic Processes in Micro-Organisms* by Drs. Marjory Stephenson & Ernest Frederick Gale, and *Wider Aspects of Studies of the Nutrition of Micro-Organisms* by Dr. D. D. Woods naturally fall within their places in the present volume. Again, *The Development of British Anti-Lewisite (BAL)* by Prof. Peters and his colleagues at Oxford provides an excellent example of the value of the biochemical approach to an apparently complex pathological problem, with the enzyme system as the focus of attack. Findings of the greatest theoretical and practical significance, which are ably discussed by Prof. Peters, have accrued from this work, while his collaborator, Prof. R. H. S. Thompson, deals with the *Therapeutic Applications of British Anti-Lewisite* which have subsequently been developed upon general lines. The fact that biochemistry can provide a rational treatment for the toxic conditions due to arsenic, gold and other metals, is but one of the many vindications of the theoretical approach followed by Peters and his school.

The work of Beadle, Tatum and others, on the nutritional requirements of x-ray-induced mutants of *Neurospora crassa* and other organisms, has provided a previously unexpected line of attack upon the problems of the biochemistry of intermediary metabolism, but the implications of this work are very wide, and are only now being realized. Their application to human genetics is still to be developed, but in his article on *Human Biochemical Genetics*, Mr. Tracey recalls the pioneer work of Garrod and others upon inborn errors of metabolism, the study of which has received a new impetus from the recent experimental investigations on micro-organisms.

The article by Mr. N. W. Pirie entitled *Development of Ideas on the Nature of Viruses* deals in a critical manner with some of the speculative ideas which have abounded since the pioneer work of Stanley and his colleagues on the so-called crystallization of plant viruses. But such criticisms need not detract from the significance of the results of this purely biochemical attack upon a problem which was originally one confined to pathologists or bacteriologists. The problems of immunology have provided the material for the irruption of biochemistry into another field not previously

explored from such an angle, and this aspect of the work is ably discussed by Prof. A. Wormall in his article *Contributions of Chemistry to the Problems of Immunology*. The articles on Fibrous Proteins as Components of Biological Systems and on Some Newer Knowledge of Plasma Proteins, by Dr. Kenneth Bailey and Dr. R. A. Kekwick respectively, describe work which is mainly directed towards the problem of the identity and nature of the building-stones of biological systems, while *Amino-Acids in Nutrition* by Dr. A. Neuberger brings us back once more to the dynamic aspects of biological equilibria.

The articles in the present number of the *British Medical Bulletin* illustrate the significance of the progress in medical science towards the study of smaller and smaller units. In the early days the organ was the element for study, but the work of Bichat on the fundamental concept of tissues and later the investigations of Virchow elaborated the idea of the cell as the essential unit in all tissues and organs. Modern biochemistry has developed this idea still further, and now regards the underlying fundamental unit as the molecule. It is from this idea that the unifying influence of bio-

chemistry upon the diverse phenomena of biology and medicine springs. Whatever their origin, cells are found to have certain elements of structure in common. They all contain proteins, fats and carbohydrates. Their metabolic processes are catalyzed by enzymes which are surprisingly similar in nature and function wherever they may be found throughout the species. Enzymes co-operate with co-enzymes, which again are widespread to a surprising degree. Co-enzymes in many instances are constructed from essential constituents of the food, hitherto known as vitamins when human or animal nutrition is under consideration. That many micro-organisms nutritionally depend upon a supply of such vitamins has been a discovery of great practical and theoretical significance.

By thus revealing a common ground-plan among so many different biological systems, the biochemist has provided an understanding to the solution of many medical problems, the approach to which could previously be only empirical. To such developments the biologist and the medical man, no less than the biochemist, owe an immense debt to the intuitive insight of Frederick Gowland Hopkins.

F. G. Young

THE EDITOR wishes to acknowledge the valuable help given by Professor F. G. Young of the Department of Biochemistry, University College, London, in the planning of the Symposium of this number and for writing the Introduction.

\* \* \*

We would also like to draw the attention of our readers, especially of those abroad, to the article by Dr. F. H. K. Green which appears at the beginning of Part II of this number (page 352), on the origin, constitution and functions of the Medical Research Council. During the war Dr. Green was secretary of the MRC War Wounds Committee and of the Therapeutic Trials Committee and is now Assistant Secretary to the Council. This authoritative article, with its useful table showing the principal research establishments of the MRC, should prove of great value to those interested in medical research in Great Britain.

SIR F. GOWLAND HOPKINS

1861-1947

1194

## SIR FREDERICK GOWLAND HOPKINS O.M. P.R.S.

JOSEPH AND DOROTHY NEEDHAM

In writing something on "Hoppy" (as he was universally known in the world of biochemists) by way of introduction to this special number of the *British Medical Bulletin*, it will be our aim to try to give some impression, however faint, of his personality, supplementing the accounts of his life and work which have already appeared.<sup>1</sup> Our excuse may be that for more than twenty-five years he stood *in loco parentis* to us, as to all other Cambridge biochemists of our generation.

It is therefore not necessary to repeat in great detail the story of his life and principal investigations—his early work in a toxicological laboratory, his medical training at Guy's Hospital, his invitation to Cambridge in 1898 by Sir Michael Foster, the tutorship at Emmanuel, the praelectorship at Trinity, a chair in 1914, a great new building in 1925, the Order of Merit, the Nobel Prize, and so on. Widely known, too, is the course of his researches; first on gout and uric acid and the pigments of butterflies, then on amino-acids with the discovery of tryptophan (with Cole), then on the accessory food-factors now called vitamins, next to muscle-contraction and lactic acid (with Fletcher); and finally to oxydo-reductions and the discovery of glutathione—a subject which kept his interest during most of the period between the two World Wars—until at the end he returned with more precise analysis to his earliest interest, the pterine pigments of lepidoptera, now with much wider physiological significance.

The first twenty years of Hopkins' work and teaching were carried out in an extremely old and uncomfortable building in Corn Exchange Street, many of the rooms of which were semi-cellars. We can well remember this, as it lasted in partial use until the construction of the present Institute in Tennis Court Road in 1924. Much of the equipment was antique, too; for example, a centrifuge which was mounted on boards and had no arrangements for securing it to a base, used to ride all over the floor of a cellar when in operation. It was in these rooms that the rat-colony was kept; its entire feeding and upkeep during the classical investigations on vitamins in 1910 were done by Hopkins himself. Upstairs was the shelf on which had stood in the sunlight the bottle of acetic acid which had led to the discovery of the glyoxylic test for tryptophan. Below were the ancient benches on which "Charles" had cut up the quarters of horses towards the end of World War I for the extraction of glutathione.

The year 1920 saw expansion into a building hardly less

queer than that in Corn Exchange Street, namely an old chapel in Downing Place where the space level with the galleries had been specially floored. A bridge connected the main part with an annexe in which Hopkins himself worked. Here developed all the lines of research which were afterwards to characterize Hopkins' institute—intermediary metabolism, especially that of sulphur compounds; bacterial metabolism; the chemistry of muscular contraction; the precise physico-chemical study of enzymes and pigments; and embryological and zoological biochemistry.

By no means the least important of the rooms in this building was the library (Hopkins was always ready to die in the last ditch for the departmental-library principle) and tea-room. Throughout the fifty years of Hopkins' work at Cambridge there were held weekly or fortnightly tea-club meetings, at which one or other of the research-workers would give an account of work in progress or nearing completion. The standard of criticism at these meetings was extremely severe, so that the speaker met with more rational and constructive comment there than he was ever likely to encounter at subsequent meetings of public societies to which he might communicate his work. It was at these meetings that Hopkins' genius particularly showed itself; he invariably made every paper seem interesting, what the author might have dully presented he illuminated with a flow of historical allusions and valuable suggestions springing from his profound intuitive insight into the structure and functions of the living cell. No one could speak or act as if blinded by passion or prejudice when in the presence of a leader so objective yet so encouraging, so affectionate yet so penetratingly quizzical, whose insight was conveyed by hints and odd remarks to which no one could object, but which one disregarded at one's peril.

Perhaps these meetings were so searchingly critical precisely because of "Hoppy's" own extraordinary charm and kindness. Under his aegis almost anything could be said without fear of offence. This was, in fact, his most outstanding personal quality; he was a living embodiment of the Confucian maxim that one should behave to everybody as one receiving a great guest. The humblest laboratory assistant or the youngest research worker was always sure of a welcome, and a hearing, unhurried and attentive, much longer than he was likely to get from any other scientific man of the same standing or generation. Hopkins had faith in people. Colleagues were known to remark lightly that "All Hoppy's geese are swans", but they forgot that there is an induction process by which certain geese may be turned into swans if given the hormone of encouragement.

It was undoubtedly for these reasons that when we attempted recently to recapture some characteristic sayings of Hopkins, some "famous remarks" of Johnsonian flavour, we found it quite impossible to do so. This fact is of interest in itself. He was too courteous, in a way too self-effacing, to allow himself to be the author of epigrams which might hurt anyone; he expressed himself so diffidently, and above all he spent so much of his time listening to other people, that his essence cannot be treasured in a few *bons mots*. He was a great giver and receiver of moral support—if he gave freely of it to all his collaborators and colleagues, he also needed it, for he frequently passed through periods of depression. And this was one of his

<sup>1</sup> E.g.—*Brit. med. J.* 1947, 1, 742  
*Lancet*, 1947, 1, 728  
*Nature, Lond.* 1947, 160, 44

secrets, that he was open to receive it from the most junior of his research workers, so that they did not feel he was encouraging them like some *deus ex machina*, but as one of themselves; in other words he fully understood and practised the great doctrine of leadership *from within* and not from above.

Anyone who obtained the impression from what has been said that Hopkins had a colourless personality would indeed be wide of the mark. He did not say things that make the stuff of anecdotes, he did not speak much on the radio or appear prominently in the public press, he did not engage in polemics. But he had the knack of surrounding himself with people of striking personality, such as A. Szent-Györgyi (the Hungarian Nobel Prize winner and discoverer of the chemical constitution of vitamin C), J. B. S. Haldane (afterwards Professor of Genetics at London), Marjory Stephenson (one of the first women to become F.R.S.), T. S. Hele (later Master of Emmanuel and Vice-Chancellor of the University), etc., etc. But nothing ever put "Hoppy" in the shade. No one could fail to recognize in the little figure, rubbing its eyes in a characteristic gesture during a conference, loitering with overcoat unbuttoned in the hall, or proceeding with ruminative walk past the colleges, the authentic gold of intellectual inspiration, the *Fundator et Primus Abbas* of biochemistry in England.

The pattern completes itself when we look at the various practices which he established. Contrary to what has been known in some English and many continental laboratories, Hopkins would never put his name to any scientific paper for which he had not himself done a considerable part of the manual and experimental work involved. Although no doubt great results are to be achieved by the direction of large teams, he was never interested in forcing the diverse talents of his younger colleagues into the funnel of one problem, as he could well have done in such matters as vitamins or oxydo-reductions. On the contrary, he was always looking out for originality, and encouraged the smallest sprouts of it to develop in their own way. Sometimes a young worker would devote himself to some subject which "the Professor" had initiated and then dropped, and make a life-work of it—this happened with vitamins, with muscle-biochemistry, and with oxidation-reduction enzymes. In other cases, a young worker would start something new with every possible encouragement from Hopkins—this happened with the metabolic chemistry of micro-organisms, with embryological biochemistry, and with the study of plant-pigments. One of us certainly will never forget how quickly Hopkins appreciated the fascination of the hen's egg as a closed-box system of chemical transformations; he said that there were many lifetimes of work in it, and it put him in mind of a discussion he had had at Michael Foster's breakfast-table some twenty years earlier.

If, then, Hopkins' outstanding personal characteristic was a universal courtesy, even a capacity to suffer fools gladly (knowing that some fools may change into wise men in the process), what was his outstanding intellectual characteristic? Originally, we believe, it was a deep intuitive faith in the explicability of the biochemistry of the living cell—the same faith which once inspired Aristotle when, in the face of the apparently infinite complexity of living forms, he nevertheless maintained that it was possible to classify them, and proceeded to do so in at least a pre-

liminary way. Having in mind what we know now about the numbers of species of arthropods, and how little we yet know about the physiology of invertebrates in general, Aristotle's faith seems indeed extraordinary. Hopkins was of the same lineage, for at a time when it could be said, or had until shortly before been currently said, "*Tierchemie ist nur Schmierchemie*", he knew better. He was not only an organic chemist who could isolate substances from living tissues and study their chemical structure; he was a *biochemist* who could in imagination perform the synthetic process of building back the living cell and of visualizing what processes were going on in it. And this was all the more extraordinary in that he was himself not the direct pupil of any of the pioneers of biochemistry. Here came into play his intuition. At a relatively late period one of the more provocative of the younger research workers opined that "Hoppy" was not a great experimentalist, and on being asked why, replied that it was because he did not need to do experiments, he knew which way the cat would jump beforehand, and only needed to carry out practical work to demonstrate what his insight had already told him was true. This was not at all an unfair judgement, though paradoxical in that Hopkins was in fact a brilliant practical chemical manipulator and experimentalist; a most accomplished laboratory worker. By 1914 Hopkins had transmuted the old German jibe into the famous definition: "Life is a dynamic equilibrium in a polyphasic system."

As to scientific literature, Hopkins was by no means a despiser of it, as some eminent experimentalists have been, trusting in their own originality and in the mistakes of others. He read a great deal, and often inspired his listeners with enthusiasm for neglected pioneers such as Thudichum, the investigator of the brain lipids; or de Rey Pailhade, the discoverer of "phylthione", the hypothetical substance which preceded the real glutathione. In later stages, the walls of the laboratory were decorated with engravings of Lavoisier, Harvey, Boyle, Hales, Scheele, etc., together with an original manuscript of Liebig. Hopkins' lectures to the advanced class were often largely historical. One characteristic which all his pupils remember was his trick of waving about in a beaker of water the feather of a tropical bird, from which the water-soluble pigment turacin comes out—anyone who was not interested in such a phenomenon would, he used to say, never make a biochemist. It was equally characteristic of him that when, on one occasion, one of the more phlegmatic young research-workers was not perceptibly excited by it, he remarked that of course one must in this test make allowances for temperament. At the very close of his life, when he was perhaps remembering more of his youth, he told another pterine investigator that as a boy he had taken the wings of a butterfly and heated them in a spoon on the kitchen range of his home; when the pigments dissolved in the water he was extremely astonished and delighted.

So far as we can remember Hopkins had no particular hobby except reading, which he did largely in a fairly unselective way, on all kinds of subjects, such as history, archaeology and the like. One of his daughters was destined to become a distinguished archaeologist, doubtless not without some encouragement from these broad interests of her father's. Though he never visited any of the remoter parts of the world, he always took a great interest in people

## BIOCHEMICAL INTEGRATION IN CELLULAR FUNCTION

ERNEST BALDWIN B.A. Ph.D.

*Biochemical Laboratory, Cambridge*

- 1 Intracellular dynamics
- 2 Source of muscular energy
  - a Phosphorylation
  - b Glycolysis
  - c Oxidation
- 3 Extramuscular energy

"La vie," declared Lavoisier in 1780, "est une fonction chimique". Liebig, echoing Lavoisier's belief, in an address to the Chemical Section of the British Association in 1837, expressed his conviction that in the newly-founded science of organic chemistry, biology could find its most powerful ally. But the cry of the chemists that "Tierchemie ist Schmierchemie", and the obscurantist tactics of many biologists, delayed the large-scale application of chemical methods to biological problems for more than 50 years. A few, notably Voit and his pupil Rubner, followed in Liebig's footsteps and, in 1894, Rubner could announce his calorimetric demonstration that the amount of energy expended

by a living organism is exactly equivalent to the energy set free by metabolism within the body; that living, like non-living systems, conform to the principle of the conservation of energy.

### 1. Intracellular Dynamics

For the early development of its dynamic side, biochemistry owes its greatest debt to Gowland Hopkins, whose recent death has deprived us of the subject's most powerful protagonist and its most inspired and inspiring leader. Of his many speeches and addresses perhaps none was more significant or far-sighted than that delivered to the Physiological Section of the British Association in 1913. Setting aside the "vital forces" as an unnecessary postulate, he pointed out with incisive clarity the greatness of the part the organic chemist could play in the development of biochemistry. "One reason", he said,

which has led the organic chemist to avert his mind from the problems of Biochemistry is an obsession that the really significant happenings in the animal body are concerned in the main with substances of such high molecular weight and consequent vagueness of molecular structure as to make their reactions impossible of study by his available and accurate methods . . . So far from this being the case, recent progress points in the clearest way to the fact that the molecules with which a most important and significant part of the chemical dynamics is concerned are of a comparatively simple character.

Later in the same address came what is perhaps Hopkins' most celebrated utterance:

On ultimate analysis, we can hardly speak at all of living matter in the cell; or at any rate we cannot, without gross misuse of terms, speak of the cell life as being associated with any one particular type of molecule. Its life is the expression of a particular dynamic equilibrium which obtains in a polyphasic system . . . but "life", as we instinctively define it, is a property of the cell as a whole, because it depends upon the organisation of processes, upon the equilibrium displayed by the totality of the co-existing phases.

### FREDERICK GOWLAND HOPKINS

*Continued from page 300*

who came from them and welcomed them to his laboratory, which thus acquired and maintained throughout a thoroughly international character. Before the first World War he had a number of Japanese pupils, but later only one—an odd character who caused some confusion in the laboratory by coming in late at night to work (it was typical of the institute that it was always available for work all night) and hanging his coat and hat on the thermostat-rod of an incubator. China and India were represented and North and South America very much so, while all the countries of Europe and the Near East contributed at one time or another their quota of investigators, as did all the Dominions of the British Commonwealth. Frequently a postcard would arrive filled with signatures from bodies such as the "Hoppy Club of San Francisco". Correspondingly, the presentation volume *Perspectives in biochemistry* which he received upon the occasion of his 75th birthday, was a success altogether unexpected by its publishers, the Cambridge University Press, and went into three editions.

From what has already been said, it will be obvious that Hopkins was naturally a democrat. We shall always remember a meeting, held in 1942, which was designed to inform all those working in the institute, including especially the laboratory assistants and cleaners, in semi-popular language, of what exactly were the various pieces of war research being carried out in the institute. Each speaker was given only three minutes. It was expected and understood that the Professor, in view of his age

and eminence, would take longer; but no, the Nobel Prizewinner and ex-President of the Royal Society said his say in exactly the same time as all the others. The meeting achieved its purpose of intensifying the war effort of the institute.

A perfectly sympathetic personality is not usually achieved without cost. There is no doubt that Hopkins had a very severe struggle in his early years, and at the end of his Emmanuel tutorship he was so overworked that he suffered a kind of nervous breakdown for a short time. Daily, hourly, as everyone must with something new to give to the world, he battled with the philistines. Unfortunately, in his very last years he also had much to suffer, when increasing physical disabilities coexisted with undiminished retention of intellectual power and curiosity. But it all resulted in a personality which drew from his colleagues not only intellectual admiration but deep affection and even veneration. So many of the Taoist paradoxes were found to be applicable to Hopkins—"The Sage follows after things, in order that he may control them"—"The Sage has no personal wishes, therefore all his desires are fulfilled". Inspired by his intuitive understanding of the living cell, Hopkins stood self-forgetful in front of the facts. One can see him now, at the top of the stairs, coat open and hands in pockets, backed by his technical assistant, with cigarette drooping over the centrifuge tubes; head quizzically slightly at an angle, benignly smiling, enquiring about the latest results. One never came across anybody at all like him, and now one is sure one never will.

This insistence upon the essentially dynamic nature of intracellular affairs has led in our own time to a new knowledge and understanding of metabolism in relation to physiological function, and in the cells of muscle above all other tissues we are beginning to see a closely integrated picture of the association between chemical composition, intermediary metabolism, and cellular function. In this article an attempt is made to show how, upon the foundations laid by Hopkins himself, our present knowledge has been built.

## 2. Source of Muscular Energy

Already, in collaboration with Fletcher, Hopkins had provided a starting-point by supplying the first unequivocal evidence that, under anaerobic conditions, muscular activity is associated with the formation of lactic acid. This pioneer work was soon followed by demonstrations from other laboratories of quantitative relationships between work done, heat or tension developed in muscle, and the amounts of glycogen disappearing and lactic acid formed. That glycolysis furnishes the ultimate source of contraction-energy was established beyond doubt. Later, however, Lundsgaard discovered that a muscle, previously poisoned with iodoacetate, is capable of normal contraction without the formation of any lactic acid whatsoever. Iodoacetate prevents glycolysis completely, but does not interfere with the decomposition of phosphagen (creatine phosphate), a normal muscle-constituent discovered about three years earlier by the Eggletons in Britain and by Fiske & Subbarow in the USA. Quantitative relationships between work done and the amount of phosphagen decomposed in iodoacetate-poisoned muscle were next established and, since such a muscle goes into rigor as soon as its supplies of phosphagen are exhausted, it appeared that the hydrolysis of phosphagen is a more-immediate source of contraction-energy than glycolysis itself.

A new mine was sprung when Lohmann showed conclusively that, if phosphagen is added to a dialyzed muscle-extract, it fails to undergo hydrolysis. If adenylic acid is added to the extract, phosphagen breaks down, but not by hydrolysis as had been anticipated. Instead, its phosphate radical is transferred to the adenylic acid, with formation of free creatine and adenosine triphosphate (ATP). Now resting muscle contains ATP but no adenylic acid. It therefore follows that ATP must be decomposed before any breakdown of phosphagen can take place, so that yet another process is interposed between glycolysis, which is the ultimate energy-source, and contraction itself. Englehardt & Lubimowa subsequently discovered that the enzyme catalyzing the decomposition of ATP is identical with the contractile protein of the muscle, myosin, and thus established

a close logical connexion between the contractile material of the cell, the enzyme that liberates the contraction-energy, and the immediate source of that energy. In passing, it should be noticed that myosin catalyzes the removal of only one of the three phosphate-radicals of adenosine triphosphate,

FIG. 1. SCHEME TO ILLUSTRATE THE REACTIONS INVOLVED IN GLYCOLYSIS\*

The part played by phosphagen is omitted for the sake of clarity. The enzymes and coenzymes involved are listed in Table I.

TABLE I. GLYCOLYSIS: ENZYMES, COENZYMES AND INHIBITORS\* (see also fig. 1)

Reaction	Enzyme	Coenzyme
1	Phosphorylase	$-\text{PO}_3\text{H}_2$
2	Phosphoglucumutase	—
3	Oxoisomerase	—
4	Phosphohexokinase	ATP
5	Zymohehexase	—
6	Phosphotriose isomerase	—
7	? Spontaneous	$-\text{PO}_3\text{H}_2$
8	Triosephosphate dehydrogenase	Coenzyme I
9	Unnamed phosphokinase	ADP
10	Phosphoglyceromutase	—
11	Enolase	Mg ions
12	Unnamed phosphokinase	ADP
13	? Spontaneous	—
14	Lactic dehydrogenase	Coenzyme I

\* Reprinted from Baldwin, "Dynamic aspects of biochemistry", fig. 28, table 26, by kind permission of the Cambridge University Press.

so that the product is not adenylic acid (adenosine monophosphate) but the corresponding adenosine diphosphate (ADP). This compound, like adenylic acid itself, can be phosphorylated by reaction with phosphagen.

"... The energy of the muscle", said Hopkins in the address already quoted, "is continuously supplied by the progress of organic reactions, and for a full understanding of events we need to know every detail of their course". As far as anaerobic events are concerned, such a knowledge has been gradually accumulated by the work of many investigators, notably by Meyerhof, Parnas and D. M. Needham, and we are now able to give what we believe to be a fairly complete account of the reactions leading from glycogen to lactic acid in the muscle. The reaction-sequence as we now believe it to take place is summarized in fig. 1. It involves some dozen enzymes and half-a-dozen or more coenzymes. We may well exclaim with Hopkins, "What indeed are we to think of a chemical system in which so great an array of distinct catalysing agents is present, or potentially present?" But, "Underlying the extreme complexity we may discover a simplicity which now escapes us." Hopkins' intuition here, as in so many cases, has been amply justified, this time by the discovery that the molecules of adenosine triphosphate and certain other compounds of phosphoric acid possess some very peculiar properties.

#### *a. Phosphorylation*

The ATP molecule can be visualized as consisting of a molecule of adenosine to which are attached in series three phosphate radicals. If the terminal phosphate radical is removed by hydrolysis there is an output of heat amounting to some 12,000 calories for each gram-molecule of phosphate removed. A similarly high yield of energy is obtained if the second linkage is ruptured, but the removal of the last phosphate radical is attended by a comparatively trivial thermal change, amounting in this case to only about 2,000 calories per gram-molecule. Lipmann therefore speaks of the first two phosphate linkages as "energy-rich bonds", as contrasted with the third, an "energy-poor bond", which is typical of phosphate-ester bonds in general. Still more important was the discovery, due in the first instance to Lohmann, that these "energy-rich" phosphate radicals can, under certain conditions, be transferred from one molecule to another, without the loss of any energy whatsoever. Thus, in the presence of the muscle enzymes, phosphagen, which also contains an energy-rich phosphate-bond, can transfer its phosphate radical, together with the energy with which it is associated, to a molecule of ADP so that a new molecule of ATP is produced. Representing the phosphate radical by P and the energy-rich bonds by the special symbol  $\sim$ , this process can be represented by the following equation (C = creatine):

Picture now the events following upon the arrival of a stimulus in an iodoacetate-poisoned muscle-cell. In some manner of which we are still ignorant, the muscle myosin gains access to and acts upon ATP, its molecules shortening as it does so, so that the energy of the terminal energy-rich phosphate bonds of the ATP molecules appears largely in the form of mechanical work. The products of the reaction are ADP and free, inorganic phosphate. As fast as ADP is produced it is re-phosphorylated and re-energized at the

expense of phosphagen, and this process of alternate decomposition and reconstitution of ATP continues until activity ceases or the phosphagen supplies are exhausted, in which case the muscle goes into rigor. The amount of stored energy-rich phosphate present in the form of phosphagen is four or five times greater than that initially available in the form of ATP, so that phosphagen must clearly be regarded as a device which allows the cell to remain in full activity until glycolysis, which of course takes place in the normal unpoisoned muscle, gets under way. Glycolysis, indeed, is known to be relatively slow in getting started although, once established, it can resynthesize ATP from ADP as fast as, or faster than the reaction with phosphagen. Apart from a few other types, such as the electric cells of certain fishes, only the cells of muscle are normally called upon for sudden response in the form of a very high rate of energy-output, and in all such cells we find that smaller or larger stores of phosphagen are present. Other cells, such as those of yeast and liver, which are characterized by more leisurely forms of activity, use essentially the same glycolytic mechanisms, but contain no phosphagen, and the latter must therefore be regarded as a specialized, adaptive mechanism that tides the muscle-cell over the interval between the onset of activity and the full establishment of glycolysis, an adaptation without which the sustained high level of energy-output so characteristic of muscle could not be achieved.

#### *b. Glycolysis*

What now of the glycolytic processes? Examination of fig. 1 shows that for each 6-carbon unit of glycogen broken down to lactic acid, 3 new molecules of ATP are formed from ADP. The synthesis of ATP from a compound of lower energy-content calls for the provision of energy. The chemist, faced with the task of achieving an energy-consuming synthesis, resorts to the use of high temperatures, strong acids, alkalis and other powerful reagents, resources that are denied to the living cell. It follows, therefore, that the reactions immediately preceding the formation of new molecules of ATP must be of fundamental biochemical significance. One of these reactions (reaction 8) consists in a simple dehydrogenation and the second (reaction 11) in a dehydration. The products of these reactions, unlike their precursors, contain energy-rich phosphate bonds, and it is by the transference of these to ADP that the new molecules of ATP are formed. The energy which becomes as it were "concentrated" in the newly-formed energy-rich bonds arises, of course, from the intrinsic chemical energy of the precursors, becoming "concentrated" in the energy-rich bonds as a result of the intramolecular rearrangements catalyzed by the muscle enzymes. Thus, through the reactions of glycolysis, the chemical energy of the stored glycogen of the cell is made available for transfer to ATP, the immediate energy-source of muscular contraction. There is, then, an unexpected simplicity behind the agglomeration of reactions that makes up the glycolytic process, which now appears essentially as a mechanism for the generation of new energy-rich bonds which, by transference to the ADP-ATP system, can be put to physiological service by the cell.

How nicely the metabolism is integrated with the functional needs of the cell can be appreciated from the following considerations. The first energy-significant reaction taking place on the arrival of a stimulus at the muscle-cell consists

in the disruption of ATP by the muscle myosin, the products of the reaction being ADP and inorganic phosphate. The former is promptly re-phosphorylated at the expense of phosphagen, leaving free inorganic phosphate in the milieu. Now, as fig. 1 shows, inorganic phosphate is an indispensable reactant at two points in the glycolytic reaction-chain, viz. at reactions 1 and 7. Glycolysis cannot therefore proceed unless free phosphate is available, but when the cell enters into activity and free phosphate becomes available, glycolysis begins and continues as long as any free phosphate remains. Once activity has commenced, therefore, glycolysis continues and, even when activity has ceased, still continues for a short period, until all the available phosphate has been removed, the normal resting level of ATP has been restored, and the resting stores of phosphagen replenished (see also table I).

### c. Oxidation

So far we have considered muscle only under anaerobic conditions. In the more normal state of virtually complete aerobiosis no lactic acid is produced; its immediate precursor, pyruvic acid, is completely oxidized to carbon dioxide and water, instead of being reduced. Our present knowledge of the oxidative processes is far less complete than that of the earlier anaerobic phase, but certain facts have nevertheless been established. Many of the intermediate reactions are known and it has been established that oxidation, like glycolysis, is associated with the generation of new energy-rich bonds and their transference to ADP. Recent estimates put the yield at about 40 to 50 such bonds for each 6-carbon unit of glycogen oxidized, as contrasted with the 3 bonds generated when a similar unit is glycolyzed. This means, in effect, that of the total available energy of the glycogen-store, the muscle enzymes can "capture" about 70 % in the form of ATP when working aerobically.

### 3. Extramuscular Energy

As has been mentioned, cells of kinds other than muscle also possess most or all of the catalytic equipment involved in glycolysis and oxidation. Here, as in muscle itself, the metabolic degradation of carbohydrate—and there can be little doubt that the same is true of the catabolism of fats—is associated with the generation of new energy-rich bonds and the synthesis of ATP. The question may therefore be asked: why, in cells that do not do mechanical work, do we find catalytic machinery that appears to be uniquely directed towards the synthesis of large amounts of this very peculiar compound? The answer is not far to seek. It is now known that ATP is not the immediate energy-source for muscular contraction alone: on the contrary, it appears to be the essential go-between in all the energy-producing and energy-consuming processes in cells of every kind. Thus, to take but a single example, glucose can be neither metabolized nor stored in the form of glycogen or starch without first being "primed", i.e. raised to a higher energy-level. This process of "priming" is accomplished by the transference

of phosphate to the glucose molecule from a molecule of ATP, a reaction that is catalyzed by the enzyme hexokinase. "Priming" is a wasteful process from the energetic point of view, for only some 20 % to 30 % of the energy lost to the ATP system finds its way into the newly-formed molecule of glucose-6-phosphate. Nevertheless, by undergoing an isomerization catalyzed by phosphoglucomutase, the 6-phosphate can be converted into  $\alpha$ -glucose-1-phosphate, which is the raw material for the enzymic synthesis of glycogen and starch (reversal of reaction 1). Alternatively the glucose-6-phosphate may be metabolized, but if it goes along the pathway of glycolysis an isomerization is again necessary, followed by a further "priming reaction" to yield fructofuranose-1 : 6-diphosphate (see reactions 3 and 4) before the hexose molecule becomes sufficiently unstable to be split by the enzymes of the cell.

It is a matter of great clinical interest in this connexion that it is to suppression of this "priming" process that the fundamental metabolic breakdown in diabetes mellitus is apparently due. Free glucose cannot be metabolized or stored unless it can first be "primed" by reaction with ATP under the influence of hexokinase. This enzyme is powerfully inhibited by a substance secreted by the anterior pituitary body, which accordingly opposes the storage and metabolism of glucose. Insulin acts by releasing the enzyme from the inhibition caused by the pituitary substance, and the activity of hexokinase is determined by the balance between the concentrations of the two hormones.

The energy-rich bonds of ATP, then, are of manifold importance. They furnish the immediate energy-source for muscular activity and they provide the "priming energy" necessary for the initiation of glucose-metabolism. Very possibly they play a similar part in the breakdown of fatty materials. They provide the energy needed for the synthesis of complex substances such as starch and glycogen from simpler units such as glucose, and there is evidence that they are also involved in the biosynthesis of many simpler compounds such as acetylcholine, glutamine, and hippuric acid. It is believed, moreover, that ATP plays an important part in the performance of the osmotic work necessary for selective absorption of glucose from the alimentary canal, and for its reabsorption from the glomerular filtrate by the renal tubule. It appears to be present and to play an important part in living organisms of every kind and, so far at any rate, no other substance of comparable importance in biological energetics has been brought to light.

\* \* \*

The knowledge and the discoveries so briefly reviewed in this article form but a minute fraction of the harvest gathered in by biochemistry within the last 30 years. That these discoveries, and the detection of so much simplicity behind a welter of detail and apparent complexity, should have been achieved during his own lifetime provides proof enough, should it be needed, of the inspiration of Hopkins' foresight and vision.

## METABOLIC PROCESSES IN MICRO-ORGANISMS

MARJORY STEPHENSON Sc.D. F.R.S.

ERNEST FREDERICK GALE Sc.D.

*Medical Research Council Unit for Microbiological Chemistry  
Biochemical Laboratory, Cambridge*

- 1 Anabolic processes
  - a Fermentation and phosphorylation
  - b Cell-building: vitamin needs
  - c Mutation: gene-control
- 2 Metabolic disturbance in the infected host
- 3 Disturbance of the metabolism of the parasite by chemotherapy

Microbes, particularly bacteria, are unique among biological forms in that study of their metabolic activity preceded the knowledge of their existence. Fermentation and infective disease have both been studied from the earliest times, but the causal agents in both cases awaited the development of the microscope and the master-mind of Pasteur to relate them conclusively together. Pasteur indeed carried this correlation along the first stage of its journey; he believed that both effects were linked with the physiological processes and needs of the causative microbe, but the unravelling of the mechanisms by which the metabolic processes of the cell produced the varying phenomena of fermentation and disease awaited later exploration.

### 1. Anabolic Processes

Pioneer work in elucidating the biochemical mechanisms by which the microbial cell brings about the chemical events of fermentation was due to Arthur Harden. In his classical studies on the fermentations by *Bact. coli* (Harden 1901) and *B. lactis aerogenes* (Harden & Walpole, 1906) he was the first to make a quantitative study of the products of a mixed bacterial fermentation with the purpose (i) of accounting quantitatively for the substrate fermented in the products of fermentation and (ii) of discovering by what intermediate steps the final stable end-products were produced from the original hexose. He thus laid the foundation on which later workers have built the modern structure of fermentation-chemistry.

#### a. Fermentation and Phosphorylation

Harden's second piece of pioneering was the discovery that fermentation was linked with the production of phosphate esters (Harden, 1932). It would be hard to exaggerate the importance of this observation; through its development it is now known (Barron, 1943) that all fermentations occur through intramolecular rearrangement, not of 6- and 3-carbon compounds as was thought earlier,

but of their phosphate esters through the system of intermediate reactions known as the Embden-Meyerhof-Parnas cycle. This, with minor variations, additions, and modifications, has now been proved to be the scheme into which fit all the ever-growing company of fermentations brought about by bacteria, moulds and other unicellular organisms, including free-living animal cells like spermatozoa. In this scheme, the fructose diphosphate discovered and isolated by Harden (1932, p. 58) holds a key position.

But the phosphorylations first studied by Harden have an even more profound biological meaning than that of forming the framework within which fermentations occur. Convergent evidence supplied by several workers (Meyerhof & Suranyi, 1927; Needham & Pillai, 1937) and ably summarized and extended by Lipmann (1941) has shown that the entry of phosphate into the fermentation-cycle results in the formation of phosphate-ester links whose energy content is c. 3,000 cal./mol.; and that the result of the changes which occur during the cycle is to concentrate the energy derived from the sugar molecule into an energy-rich bond in phosphopyruvic acid, so that the rupture of phosphate from this substance liberates c. 12,000 cal./mol. The fermentation-cycle thus provides the mechanism for concentrating the energy from the carbohydrate molecule into a form from which it can be either liberated or stored within the cell in the energy-rich bonds of adenosine pyrophosphate, whence it can be released to serve the anabolic processes in cell-synthesis. Even chemosynthetic (autotrophic) bacteria appear to work in this way, the energy liberated by the oxidation of sulphur being stored as phosphate esters to be used subsequently for the reduction of CO<sub>2</sub> required in the synthesis of carbohydrate and hence of other cell-material (Vöglér & Umbreit, 1942).

#### b. Cell-building: Vitamin Needs

In retrospect, the mechanism by which the energy-providing systems operate seems comparatively easy to elucidate, as compared with the formidable problem of the building up of cellular material from the substrate. The enzymes and coenzymes of oxidation and fermentation have now all been isolated, and their action in these processes can be followed in full detail in vitro. But between the products of digestion, whether of the animal or microbe, and the final appearance of the new cell, there remained for long a chasm of ignorance. It may fairly be claimed that the study of microbiological chemistry has played a large part in constructing the slender bridges so far thrown across this gulf. This is due largely to the greater tolerance of the microbe towards interference with its metabolic routine as compared with the more-highly-integrated animal organism, and to its much greater tendency to vary biochemically. The microbial cell shows its relationship with that of the animal in requiring for its growth and functioning the entire range of the B vitamins; in fact, several of these, e.g. biotin (Kögl & Tönnis, 1935), inositol (Eastcott, 1928) and *p*-aminobenzoic acid (Rubbo & Gillespie, 1940) were discovered in studies of microbial metabolism before their importance to the animal was recognized.

Many bacteria, yeasts and fungi are able to synthesize every member of the group, but many others, through prolonged cultivation in an environment where these compounds are present (due to the activities of animals, plants or other microbes), have lost certain synthetic powers

and require to have one or more of the vitamins supplied in their media. Such exacting organisms have furnished valuable information as to the function of the vitamin in question; grown on suboptimal concentrations of the factor, the deficient cells display subnormal activities of certain enzymes which—even in non-proliferating cells—function normally when the concentration of the factor is raised. Thus aneurin, or its pyrophosphate (vitamin  $B_1$ ), was known to be necessary for the oxidation of pyruvic acid by animal tissues and for its decarboxylation by yeasts; similar studies on bacteria by the method mentioned above have shown that it is necessary for other reactions in bacterial metabolism in which pyruvic acid is involved (Hills, 1938). To take another example: the active components of the  $B_6$  complex (pyridoxal phosphate and pyridoxamine) have been shown by this deficient-culture method to form parts of the enzymes catalyzing the transfer of amino-groups from certain amino-acids to certain keto-acids, thus possibly playing a part in the synthesis of proteins, whilst pyridoxal phosphate has been shown to act as coenzyme of the bacterial amino-acid decarboxylases (Gale, 1946). Work on yeast has shown that biotin functions in the assimilation of ammonia (Winzler, Burk & du Vigneaud, 1944), and studies of *L. plantarum* (Stephenson & Rowatt, 1947) have corroborated the observation that pantothenic acid functions in the acetylation of choline. The function of *p*-aminobenzoic acid as a vitamin was foretold through the discovery of its property of antagonizing the action of sulphonamides on bacteria (Woods, 1940). This prophecy was fulfilled within a year when it was shown to be a growth-factor for a strain of *Cl. acetobutylicum* (Rubbo & Gillespie, 1940).

### c. Mutation: Gene-control

The work of Beadle & Tatum (1941) in the USA has developed the use of the microbe—principally the mould *Neurospora crassa*—for the study of the biochemistry underlying mutation and gene-control. By the study of artificially-induced mutants they have suggested that each mutant arises by the loss of one gene which controls the production of one enzyme. If one of the enzymes involved in a chain of synthetic reactions is lost by the mutant, then the organism becomes nutritionally exacting towards the product of the step catalyzed by that enzyme. In this way, important information has been gained on the anabolic mechanisms of the cell. For example, it has been shown that anthranilic acid and indole are the serial precursors of tryptophan, the last step in the synthesis being the condensation of indole with serine (Tatum & Bonner, 1944), the same route being independently shown to hold for *Esch. coli* (Fildes, 1945). Similarly, the synthesis of arginine proceeds through ornithine and citrulline (Srb & Horowitz, 1944) whilst the immediate precursors of valine and isoleucine (Bonner, 1946) are the corresponding keto-acids.

The microbe thus supplies ideal biochemical material for the study of anabolic processes, giving results which may prove to be valid also for both animals and plants. It also promises to provide a clue to the mechanism by which the gene controls the production of enzymes and so controls the development of the cell. In the brilliant work of Avery, MacLeod & McCarty (1944) it has been shown

that the rough (non-encapsulated) Type II pneumococcus can be transformed permanently into a new type producing the polysaccharide capsule characteristic of Type III. This has been done by incorporating into the growth-medium of the rough form of the Type II organism minute amounts of a rigidly-purified desoxyribonucleic acid obtained by the disintegration of the Type III organism. This transformation seems to be equivalent to the incorporation in the Type II cell of a new gene controlling the enzymic production of the Type III polysaccharide.

## 2. Metabolic Disturbance in the Infected Host

So far we have considered problems of synthesis and growth common to all living cells, but medical science is especially interested in the mechanisms by which pathogenic organisms interfere with the metabolism of the mammalian host and cause the onset of disease. It must be admitted that here our knowledge is still fragmentary, but of recent years one or two breaches have been made in the brickwall of our ignorance. Thus certain strains of *Cl. welchii* have been shown to owe their disintegrating action on tissues to three enzymes: (i) a hyaluronidase (McClean, 1941) which disintegrates the polysaccharide hyaluronic acid, the substance forming the intercellular cementing material of tissues, and this disintegration assists the invasiveness of the organism; (ii) a lecithinase which disrupts the surface-membrane of cells and is in fact a cytolytic agent (Macfarlane & Knight 1941); (iii) a collagenase which attacks the collagen sheath of the muscle fibres, leaving behind a friable mass of fibrils with no protection (Macfarlane & MacLennan, 1945). Recent months have also witnessed the isolation in pure crystalline form of two powerful toxins, those of *Cl. botulinum* (Lavanna, McElroy & Eklund, 1946) and *Cl. tetanum* (Pillemer, Wittler & Grossberg, 1946). Both act in amazingly low concentration, L.D.50 (mouse) for the botulinum toxin being  $3.2 \times 10^{-5}$   $\mu$ g, from which it was computed that the L.D.50 for a man of average weight would be 0.12  $\mu$ g. This is the lowest concentration in which any poison is known to act. After these achievements it is probable that the disclosure of the mode of action of these toxins will not be long delayed.

## 3. Disturbance of the Metabolism of the Parasite by Chemotherapy

One of the most outstanding of recent medical advances has been in the realm of chemotherapy, a rational approach to the study of which was put forward by Fildes (1940); this was based on the idea that chemotherapeutic agents owe their activity to the similarity of their structure to that of essential metabolites whose activity they block by steric hindrance. The discovery that the sulphonamides were antagonized by *p*-aminobenzoic acid (Woods, 1940), later shown to be a growth-factor (Rubbo & Gillespie, 1940), corroborated this view and led to numerous attempts to produce chemotherapeutic agents by synthesizing analogues of other growth-factors and essential metabolites. Many such compounds have been prepared, as for example, analogues of nicotinic acid, pantothenic acid and some amino-acids by the replacement of the  $-\text{COOH}$  by  $-\text{SO}_3\text{H}$  (McIlwain & Hawking, 1943; Woolley, 1946). These compounds do indeed inhibit the growth in vitro of organisms

<sup>1</sup> [cf. *BMB* 1200, fig. 2.—Ed.]

which require the factors to which the compounds are structurally related, but so far no chemotherapeutic agents comparable in value to the sulphonamides have been produced by this means.

Another advance in the host-parasite relation comes from a different line of approach. It has long been recognized that non-spore-forming pathogens cannot long survive in the mixed microbial population of the soil. The mechanism of this biological antagonism was first investigated in a rational manner by Dubos (Dubos & Hotchkiss, 1941), who treated samples of soil with pathogenic cocci over a long period and then examined the population of the treated soil. He isolated an organism, later identified as *B. brevis*, which excretes into its environment a mixture of substances lethal or inhibitory to many other bacteria. Two substances, tyrocidin and gramicidin (Hotchkiss & Dubos, 1941; Hotchkiss, 1946), were isolated as crystalline polypeptides; the former is lethal to most bacteria and appears to act as a cytolytic agent, while the latter is bacteriostatic to gram-positive cocci. This work demonstrated how one organism can antagonize another by the excretion of a substance inhibitory towards the growth of the other. Recognition of this principle and its general exploitation has led to the production in recent years of scores of "antibiotic" substances. Many of these prove generally toxic, but at least two, namely penicillin and streptomycin (Schatz, Bugie & Waksman, 1944), are specifically toxic towards certain bacteria and can be used clinically as chemotherapeutic agents. The discovery of penicillin was an independent development following on the original observation of Fleming (Fleming, 1929) that a mould-colony excreted into the medium something which lysed staphylococcal colonies growing in the vicinity. The instability of the antibiotic proved an obstacle to its large-scale production and purification, but the obstacle was eventually overcome by Florey and his team of workers at Oxford (Chain *et al.* 1940), so that penicillin is now one of the most potent weapons available to medicine.

To the biochemist the chemotherapeutic agents are

mainly of interest as tools for the elucidation of growth-processes. The fact that they can be used clinically indicates that they act upon structures, or inhibit enzyme-systems, which are more important to the parasite than to the host, so that the elucidation of their mechanism should assist the development of our knowledge of parasitic existence. All these antibacterial substances prove to be selectively active against certain groups of bacteria; to many, the bacteria loosely classified as gram-positive prove more sensitive than the majority of gram-negative species. It has been found that the staining-complex responsible for the positive gram-reaction is a magnesium-ribonucleotide-complex residing in the surface of the organism (Henry & Stacey, 1943). It has further been found that the gram-positive cell differs from the gram-negative in that the former can assimilate certain amino-acids in the free state and concentrate them within the internal environment prior to metabolism—thus, presumably, compensating for the inability of many of these organisms to synthesize such amino-acids (Gale, 1947; Taylor, 1947). Investigation of the processes whereby the amino-acids migrate across the cell-wall against a concentration-gradient has shown that penicillin-treated cells are unable to assimilate glutamic acid and, consequently, to synthesize protein within the cell (Gale & Taylor, 1946). It has previously been shown that sulphonamides interfere with the metabolism of *p*-aminobenzoic acid and it is now known that this substance forms part of folic acid and other peptides within the cell. We have here, then, indications that the nature of chemotherapeutic interference is beginning to be revealed by the concentrated attacks of biochemistry on the structure and essential anabolism of the growing cell.

One may perhaps summarize the present position by saying that knowledge of bacterial metabolism is fundamental and crucial to the understanding of anabolic processes in general, and that its extended study is the main gateway to a comprehension of the chemical mechanism of infective disease and to the control of this by chemotherapeutic agents.

## WIDER ASPECTS OF STUDIES OF THE NUTRITION OF MICRO-ORGANISMS\*

D. D. WOODS M.A. Ph.D.

*Department of Biochemistry, University of Oxford*

- 1 Uniformity of fundamental cell-processes
  - 2 Function of essential metabolites
  - 3 Nutritional approach to bacterial chemotherapy
  - 4 Biosynthesis of essential metabolites
  - 5 Conclusion
- References

A complete understanding of the fundamental biochemistry of deficiency-diseases of animals involves the solution of two main problems. First, the precise function of the food-factor (vitamin or essential amino-acid) in cell-metabolism must be established; only in this way is it possible to determine the primary biochemical lesion resulting from lack of the factor, for it is possible that the clinical symptoms arise only indirectly from this lack. Second, the need for such factors implies that the animal in question is unable to synthesize them for itself. But this failure is not common to all organisms; plants and some micro-organisms are able to synthesize a wide variety of the substances required by animals. A detailed knowledge of the biosynthesis of these "essential metabolites" by such organisms may enable the cause of the failure in other organisms to be determined.

The main purpose of the present article is to examine what contribution the study of the nutrition of micro-organisms can make to the solution of these two problems. Work done in recent years suggests that information may be obtained which may have wide application to other cells.

### 1. UNIFORMITY OF FUNDAMENTAL CELL-PROCESSES

The development of the study of the nutrition of micro-organisms has been outlined by Knight (1945) and Fildes (1946)<sup>1</sup>. Many bacteria require for growth traces of complex organic compounds (essential growth-factors). As these substances were characterized they were found to be already known as vitamins for higher animals (e.g. aneurin, riboflavin, pyridoxin, choline). In recent years there has been an increasing tendency for this order to be reversed; factors first studied as growth-factors for micro-organisms (e.g.

nicotinic acid, pantothenic acid, biotin, folic acid, *p*-aminobenzoic acid, streptogenin<sup>2</sup>) have later been found to be important also in animal nutrition.

Some bacteria do not require growth-factors, or perhaps one or two only. Such organisms are found to synthesize the factors not required, or at any rate material with the same biological activity (Knight, 1945; Peterson & Peterson, 1945). It seems a reasonable deduction, therefore, that these factors are required for the normal metabolism of all bacteria and are recognizable as growth-factors or growth-stimulants only when the cell in question cannot synthesize them or can do so only at a suboptimal rate. The inclusive term "essential metabolite" has been proposed (Fildes, 1946) for such substances, which include various amino-acids.

The same essential metabolites are thus found to be required by animal cells and by cells of micro-organisms (bacteria, yeasts, lower fungi, protozoa). Many of them have also been implicated in the nutrition of insects and the isolated root-tips of higher plants (Knight, 1945; Peterson & Peterson, 1945). This uniformity of requirement for certain substances by cells of all types leads to the conclusion that the fundamental cell-reactions in which they are involved may be common to all cells. Thus aneurin or its phosphate esters have been found to function as coenzymes in pyruvate metabolism, e.g. oxidation by pigeon-brain (Banga, Ochoa & Peters, 1939), decarboxylation by yeast (Lohmann & Schuster, 1937), oxidation to acetic acid and CO<sub>2</sub> by *Bact. delbrueckii* (Lipmann, 1944) anaerobic and aerobic breakdown by *Staph. aureus* (Hills, 1938).

It is probable, therefore, that findings concerning the metabolic function of essential metabolites in micro-organisms will, in the main, be applicable to other cells. One important limitation must be noted. Some animal vitamins (notably the fat-soluble group and ascorbic acid) have not so far been found to be concerned in the nutrition of micro-organisms. Such substances may be required for the specialized functions of the differentiated tissues of higher organisms (e.g. vitamin D in calcification).

Micro-organisms have many advantages for the study of essential metabolites. During the stages of purification and identification, the routine biological tests give rapid results and the experimental criterion (growth) is simple to assess. Furthermore, "pure" cultures are used; in tests with animals there is always present, besides animal cells, a considerable bacterial population in the gut. Synthesis of vitamins by gut-organisms may contribute to the nutrition of the animal (Najjar & Barrett, 1945; Daft & Sebrell, 1945) and obscure the results. For later studies of metabolic function, bacterial cells deficient in a given factor may be obtained easily and rapidly by growing in a defined medium containing suboptimal amounts of the factor.

### 2. FUNCTION OF ESSENTIAL METABOLITES

It is obvious that the main function of essential amino-acids is for the synthesis of cell-proteins. Some, however, also occur in the structure of other growth-factors, e.g. glutamic acid in folic acid (Angier *et al.*, 1946) and unidentified amino-acids in streptogenin (Woolley, 1946b).

\* In a general review of this type it seemed undesirable to obscure the text by detailed references to the many hundreds of papers considered either directly or by implication. When possible, therefore, reference has been made to more detailed reviews of particular aspects, or to key-papers from which other references may be traced.

[This review was received for publication on 25 June 1947.—Ed.]

<sup>1</sup> [BMB 929]

<sup>2</sup> For work on streptogenin see Woolley (1946a) and Scott, Norris & Heuser (1947).

Members of the vitamin-B complex have been found to be involved in the structure of coenzymes (or prosthetic groups) of various enzyme-systems. The role of aneurin in pyruvate metabolism has been mentioned above. Nicotinamide appears in the di- and triphosphopyridine dinucleotide coenzymes, and riboflavin in the flavoprotein enzymes, of oxidation-systems (Green, 1941). In the present review, attention will be focussed on other members of the B complex; the examples are chosen to illustrate the general methods of approach available with micro-organisms and the varying degrees of progress made.

### General Methods of Investigation

Progress has been made in the main by the use of various combinations of five methods, which are of general application.

A. Discovery that a component of the structure of a coenzyme is identical with, or related to, a known growth-factor.

B. Study of the metabolism of cells deficient in a factor, followed by detailed study of any metabolic process which is affected. It is possible, however, that the effect obtained may be secondary; lack of the factor may affect the synthesis of another factor more directly concerned.

C. Study of the metabolism of the factor itself may provide a hint as to whether it (i) must be built up to a more complex molecule before it can function, or (ii) undergoes some reversible change whilst functioning.

D. The factor may be replaceable in growth-tests by a substance X of a different chemical type. This may suggest that the factor is concerned with the synthesis of X or vice versa.

E. Use of substances, often analogues of the factor (anti-metabolite inhibitors, *v. infra*), which may specifically inhibit the utilization of the factor and lead to a breakdown of the metabolic processes with which it is concerned.

### The Vitamin B<sub>6</sub> Group

#### Decarboxylation of amino-acids

The identification of pyridoxal phosphate<sup>3</sup> (fig. 1) as the coenzyme of various amino-acid decarboxylase enzymes of bacteria provides a striking example of the joint application of methods (A) and (B).<sup>4</sup> This work was carried out by Gale and colleagues (mainly A) and by Gunsalus and colleagues (B); it has been fully reviewed by Gale (1946). Cells of the main test-organism (*Str. faecalis* R) deficient in pyridoxin were obtained (a) from a medium containing suboptimal amounts of pyridoxin (b) from a medium in which pyridoxin was replaced by *dl*-alanine

(Bellamy & Gunsalus, 1945; Snell, 1945a). An important step forward in this research came from the observation of Snell (1944) that pyridoxal and pyridoxamine had greater growth-promoting activity for some micro-organisms than pyridoxin itself. Further support for the role of the phosphate ester comes from the finding (C) that pyridoxin, pyridoxal, and pyridoxamine can be converted to pyridoxal phosphate by organisms which can use them for growth (Bellamy, Umbreit & Gunsalus, 1945).

#### Transaminase reactions

Snell (1944, 1945b) suggested that a pyridoxal = pyridoxamine transformation might act catalytically in transamination reactions by acting as an intermediate carrier of amino-groups. It has now been found (B) that pyridoxal and pyridoxamine phosphates are both active as coenzyme with cell-free preparations of *Str. faecalis* R, catalyzing transamination between glutamic and oxaloacetic or pyruvic acids (Lichstein, Gunsalus & Umbreit, 1945; Umbreit, O'Kane & Gunsalus, 1946)

Pyridoxamine phosphate is not, however, active as codecarboxylase.

Transamination reactions also occur in animal cells. Here pyridoxal phosphate has now been found to act as coenzyme with the glutamic-aspartic and glutamic-alanine transaminases (Braunstein, Kritzmann, Gale, Tomlinson & Samarina, 1946; Ames, Sarma & Elvehjem, 1947).

#### Metabolism of tryptophan

The final stage in the synthesis of tryptophan by the mould *Neurospora* is the condensation of indole and serine (see p. 311). Pyridoxal phosphate acts as coenzyme in this condensation (Umbreit, Wood & Gunsalus, 1946). There is also evidence (see p. 312) that pyridoxin derivatives are involved in the synthesis of tryptophan by *Lactobacillus arabinosus* (Schweigert, 1947). On the catabolic side, pyridoxal phosphate has been found to be one of the coenzymes involved in the breakdown of tryptophan to indole by *Esch. coli* (Dawes, Dawson & Happold, 1947; Wood, Gunsalus & Umbreit, 1947).

With animals it is found that pyridoxin-deficient rats (B) fed with tryptophan excrete xanthurenic acid (an abnormal product). Feeding of a desoxy-analogue (E) of pyridoxin (which presumably inhibits the function of pyridoxin) leads to excretion of the same acid by both normal and deficient rats (Lepkovsky, Roboz & Haagen-Smit, 1943; Porter, Clark & Silber, 1947).

#### Synthesis of other amino-acids

With certain species of *Lactobacilli*, the growth requirement for several amino-acids is abolished if pyridoxin is present (D). In some cases CO<sub>2</sub> is also necessary. Where tested, pyridoxal and pyridoxamine were more active than pyridoxin. Since organisms growing under these conditions were shown to synthesize the amino-acids in question, it appears that pyridoxin plays an essential part in their synthesis (Stokes & Gunness, 1945; Lyman *et al.*, 1947).

FIG. 1

<sup>3</sup> The position of the phosphate group in pyridoxal phosphate is not yet clear. Recent work (Gunsalus & Umbreit, 1947) appears to exclude the possibility that the phenolic group is phosphorylated.

<sup>4</sup> Capital letters refer to the general methods outlined in the previous section.

### Conclusions

Work with bacteria shows that the biologically-active forms of pyridoxin are pyridoxal and pyridoxamine phosphates. These compounds appear to have a general coenzyme function in amino-acid metabolism (both breakdown and synthesis) and there is some evidence for a similar role in animals.

### Pantothenic acid

McIlwain (1946) has studied this factor mainly by methods (B), (C) and (E). He finds that pantothenate is metabolized (concurrently with glucose-fermentation) by organisms requiring it for growth. This metabolism is inhibited by the same pantothenate analogues (e.g. pantoyltaurine) which inhibit growth, and appears to be connected with growth-factor function. It is suggested that the metabolism may yield a substance which is essential for growth. The necessity for a coupled energy-yielding reaction suggests the formation of a more complex molecule, and this may be consistent with the finding of Lipmann *et al.* (1947), that the coenzyme for the acetylation of choline by brain-tissue is a pantothenate derivative from which pantothenate may be liberated by enzyme treatment. Stephenson & Rowatt (1947) also find that pantothenate is required for the acetylation of choline by a strain of *Lactobacillus plantarum*; suspensions of deficient cells had low activity which was much increased by pantothenate (B).

Pantothenate-deficient cells (B) of *Proteus morganii* show decreased aerobic and anaerobic metabolism of pyruvate (Dorfman, Berkman & Koser, 1942; Hills, 1943). There are also findings (D) that the tryptophan requirement of *Staph. aureus* can be met by pantothenate plus glucose (Sevag & Green, 1944), and the pantothenate requirement of *Cl. botulinum* by aneurin plus choline (Lamanna & Lewis, 1946). It is possible that pantothenate is concerned with a key-reaction (involving acetylation or acetate metabolism?) common to these systems.

### Biotin

Several studies implicate this factor in nitrogen metabolism. Biotin-deficient cells of *Saccharomyces cerevisiae* have greatly-depressed rates of respiration and fermentation (B), and these are raised by biotin plus ammonia, but not by either alone. Assimilation of ammonia from the medium by such cells was found to depend on the presence of biotin (Winzler, Burk & du Vigneaud, 1944). There is evidence (D) that biotin is involved in the synthesis of aspartic acid, since (a) the stimulating effect of biotin on the growth of *Torula cremoris* can be partially replaced by this amino-acid (Koser, Wright & Dorfman, 1942), and (b) the aspartic-acid requirement of certain lactic-acid bacteria is abolished if sufficient biotin is present. Organisms growing with biotin alone were found to contain as much aspartate as those actually grown with aspartate. Since some biotin is required even when aspartate is supplied, it follows that synthesis of this amino-acid is not the only function of the factor (Stokes, Larsen & Gunness, 1947).

### p-Aminobenzoic Acid

The role of p-aminobenzoic acid as an essential metabolite was predicted from its properties in overcoming the

inhibition of bacterial growth by sulphonamide drugs (Woods, 1940). The prediction has been fulfilled by the discovery of many micro-organisms which require this substance as an essential growth-factor (see Knight, 1945; Woods, 1947). It has also been implicated in animal nutrition (Ansbacher, 1944). Elucidation of the metabolic function of p-aminobenzoic acid should therefore throw further light on the fundamental mode of action of the sulphonamides. The original hypothesis suggested that the sulphonamides inhibit competitively enzyme-reactions involved in the utilization of p-aminobenzoic acid by the cell, and considerable information as to the nature of these reactions is now available. Since sulphonamides are inhibitors of the utilization of this factor, method (E) has yielded much information. Method (D) has been applied to organisms (including induced mutants) requiring p-aminobenzoic acid for growth, and has also been very helpful. It is possible in the space available only to summarize the present position, but a more detailed analysis of the evidence and full references are given by Woods (1947).

Folic acid is another essential metabolite for micro-organisms (and for higher animals), and the molecule is now known to contain a p-aminobenzoic-acid residue. Within a limited group of bacteria, requirement for folic-acid synthesis appears to be the only function of p-aminobenzoic acid, and to be the only point of inhibition by sulphonamides. With other bacteria, however, there is evidence that this factor is also involved in the synthesis of purines, thymine and methionine, and that sulphonamides also inhibit these functions. With the nucleic-acid derivatives it is possible that the effect occurs through the intermediate production of folic acid, but with methionine the mechanism is unknown. It may be noted that various purines and pyrimidines and methionine are also essential metabolites, and appear as growth-factors for many micro-organisms.

### 3. NUTRITIONAL APPROACH TO BACTERIAL CHEMOTHERAPY

The development of the idea that the action of drugs may be due in some cases to inhibition of an enzyme, and that this inhibition occurs by virtue of a structural relationship between the drug and the natural substrate, has been discussed by McIlwain (1943), Woolley (1946c) and Roblin (1946). The discovery that p-aminobenzoic acid overcomes the inhibition of bacterial growth by sulphonamides (to which it is structurally related) and that it is an essential metabolite for bacteria (*v. supra*), has stimulated a search for analogues of other essential metabolites which might inhibit bacterial growth in a similar manner. It was hoped that such substances (often called metabolite antagonists) might also prove to be useful chemotherapeutic agents (Fildes, 1940a). A large number of such compounds has now been tested and many of them inhibit the growth of various bacteria, usually species which require the metabolite in question as a growth-factor. On the other hand, only one or two substances with appreciable therapeutic value have so far been obtained (Roblin, 1946; Woolley, 1946c, 1947). Many other properties besides capacity to inhibit bacterial growth will determine the therapeutic value of a substance (McIlwain, 1944); amongst these are

the rates of absorption, excretion and possible destruction by the tissues of the host-animal. Furthermore, the bulk of these metabolite antagonists have been modelled on substances which are equally as important for the host-cells as for the micro-organisms (see p. 308) and are likely to inhibit important metabolic processes of both (absorption, etc. being equal). Indeed, characteristic symptoms of the corresponding vitamin-deficiency disease have been found to follow the administration to animals of several of these inhibitors (Woolley, 1946c).

In the control of bacterial infections it may often be sufficient to prevent growth for a limited period whilst the defence-mechanisms of the host cope with the situation. In these circumstances, a short-term interruption of cell-multiplication processes is less likely to do harm to the adult host than to the bacterium. It is possible, therefore, that the metabolite-antagonist approach would yield a higher dividend if it could be applied to essential metabolites more specifically concerned with cell-division, but this must await the characterization of such metabolites.

Apart from possible applications to chemotherapy, metabolite-analogues have been used with much profit as specific inhibitors in fundamental biochemical studies. A number of examples of this has been given in other sections of this review.

#### 4. BIOSYNTHESIS OF ESSENTIAL METABOLITES

It has been pointed out (p. 308) that substances recognized as growth-factors for particular micro-organisms are probably essential for the growth of most micro-organisms, the difference being that some organisms can achieve their synthesis whilst others cannot. If a number of organisms require the same growth-factor, the power to synthesize it may have failed with different organisms at different stages of the series of reactions by which the synthesis is accomplished; the provision of intermediates above the point of failure will enable the synthesis to be completed and the organism to grow. Thus ammonia, nicotinic acid, nicotinamide and nicotinamide-riboside have been proposed as intermediates in the synthesis of phosphopyridinedinucleotide coenzymes, since a series of organisms exists in which each of these substances is the simplest molecule which will support growth in the absence of the higher forms (Knight, 1945). Similar evidence can often be obtained with a single species if a number of strains or mutants, each requiring the same growth-factor, are available for study. The outstanding work of Beadle (1945) and his colleagues with induced mutants of *Neurospora* has proved the value of this technique. By x- or ultra-violet irradiation of this mould, a number of "biochemical" mutants were obtained, each differing from the parent in requiring one further growth-factor. Similar mutants have been obtained by treatment with mustard-gas or its nitrogen analogue (Horowitz *et al.*, 1946). Mutants requiring most members of the vitamin-B complex and a number of amino-acids have now been isolated. These mutants are genetically dissimilar from the parent-strain and from one another, which suggests that the synthesis of individual metabolites is controlled by distinct genes. In a number of cases (e.g. tryptophan, arginine) two or more genetically-dissimilar mutants requiring the same factor have been found, and analysis of response to possible intermediates has shown

that the synthesis has broken down at different points. Thus, individual steps in the synthesis of a growth-factor may be controlled by different genes.

Analogous biochemical mutants of bacteria have been obtained by similar treatments and by the action of bacteriophage (Roepke, Libby & Small, 1944; Tatum, 1945; Lederberg & Tatum, 1946; Anderson, 1946). With bacteria there can be no genetic analysis, and therefore no hint as to which of a number of mutants requiring the same factor are likely to be biochemically dissimilar in detail.

If an exacting organism is grown in the presence of the growth-factor required, the intermediate compound corresponding to the point of failure of the synthetic chain is sometimes formed and accumulates in the medium. Thus a nicotinamide-requiring mutant of *Neurospora* produces a substance (probably an oxypyridine carboxylic acid) which promotes the full growth of another, but genetically distinct, mutant, and is therefore probably an intermediate in the synthesis of nicotinamide (Bonner & Beadle, 1946). Accumulation of precursors may also occur when growth is limited by specific inhibitors of the utilization of a metabolite (Fildes, 1945). Such growth-inhibitions may, if competitive in nature, yield further information; addition of the product of the inhibited reaction should promote growth irrespective of the concentration of the inhibitor, or (Shive & Macow, 1946) may raise the concentration of inhibitor required if the latter also affects other reactions.

This nutritional approach to problems of biosynthesis is as yet in its infancy, but shows great promise. Limitation of space precludes a full account of its application, but the case of tryptophan will be examined since it illustrates well many of the above points.

#### Tryptophan

Evidence that anthranilic acid and indole are intermediates in the biosynthesis of this amino-acid was first obtained from observations that the tryptophan requirement of *Bact. typhosum* could be met by indole, and that of *L. arabinosus* and *L. casei* by indole or anthranilic acid (Fildes, 1940b; Snell, 1943). Tatum & Bonner (1944) then isolated two genetically-distinct mutants of *Neurospora*, each requiring tryptophan. Mutant I also grew if given indole or anthranilic acid, but Mutant II responded only to indole. Furthermore, anthranilic acid accumulated when Mutant II was grown in the presence of tryptophan or indole. The role of anthranilic acid and indole as intermediates was therefore confirmed and their order of formation established (see fig. 2). It was next found that tryptophan was produced if washed mycelium of Mutant II was incubated with indole and serine. The final stage of the synthesis is thus the direct condensation of indole and serine; pyridoxal phosphate has since been shown (see p. 309) to act as coenzyme in this reaction. Additional evidence that the scheme given in fig. 2 applies also to bacteria has been obtained by different methods. 3-Indoleacrylic acid inhibits the growth of bacteria and the inhibition is overcome non-competitively by traces of tryptophan; this substance is therefore a specific inhibitor of tryptophan synthesis. A strain of *Bact. typhosum* (trained to grow without either indole or tryptophan) was found to accumulate indole in the medium when growth was partially suppressed by indoleacrylic acid; furthermore, inhibition

FIG. 2

of growth was much reduced if serine were added (Fildes, 1945). The growth-response of *L. arabinosus* to indole has been studied by Schweigert (1947) with an amino-acid medium not containing serine. Growth was poor unless both serine (or acetate) and derivatives of pyridoxine were added. A response equivalent to that given by tryptophan was finally attained in a medium containing pyridoxin, serine and acetate; the function of acetate is not clear. Since anthranilic acid did not promote full growth even in

a casein-digest medium supplemented with pyridoxin and acetate, it follows that other substances are involved in the conversion of anthranilic acid to indole.

The final stages in the biosynthesis of tryptophan by micro-organisms are thus established with reasonable certainty and in some detail. Outstanding problems are the precise mechanism of the anthranilic-acid-indole conversion, and the nature of the precursors of the former substance. The observation (Sevag & Green, 1944) that pantothenate plus glucose can replace tryptophan for *Staph. aureus* may have some relation to these problems.

## 5. CONCLUSION

The purpose of this review has been to illustrate the contribution which studies of the nutrition of micro-organisms can make to several outstanding problems of general cell-nutrition. It is not suggested that this is the only approach, and it is clear that the results should not be taken to have general application to all cells until confirmatory evidence has been obtained. Apart from the intrinsic interest to microbiological chemistry, it does appear, however, that information obtained by relatively-simple techniques with micro-organisms may give a valuable directive for similar types of research with other cells.

## DEVELOPMENT AND THEORETICAL SIGNIFICANCE OF BRITISH ANTI-LEWISITE (BAL)

R. A. PETERS M.C. M.D. F.R.S.

*Department of Biochemistry, University of Oxford*

- 1 Biochemical lesions and the pyruvate-oxidase system
  - 2 Arsenical researches
  - 3 Further theoretical points
  - 4 General implications
- References

British Anti-Lewisite (BAL) is the name given in the USA to 2:3-dimercaptopropanol, which was developed in Oxford during the first 18 months of the war as an antidote to the arsenical vesicants (see Peters, Stocken & Thompson, 1945)<sup>47 71 74</sup>. In this account, the threads which were woven into the pattern of the final research will be sketched and some details of the behaviour of BAL itself, and of its theoretical significance, will be included. The therapeutic applications in medicine are being treated elsewhere<sup>4</sup> (Thompson, 1947)<sup>64</sup>.

Some general remarks will clarify the subsequent account; (i) Very broadly, there are three kinds of toxic arsenicals, viz. arsenite, the therapeutic arsenicals such as arsphenamine  $\text{OH} \begin{array}{c} \diagup \diagdown \\ \text{NH}_2 \end{array} \text{As} = \text{As} \begin{array}{c} \diagup \diagdown \\ \text{NH}_2 \end{array} \text{OH}$  and compounds

of significance for chemical warfare such as diphenylchloroarsine and lewisite ( $\text{CH}_3\text{Cl} : \text{CH}:\text{AsCl}_2$ ). It is a reasonable view<sup>69</sup> that the toxicity of arsphenamine is due to the oxidation-product, the trivalent arsenoxide<sup>b</sup>  $\text{OH} \begin{array}{c} \diagup \diagdown \\ \text{NH}_2 \end{array} \text{AsO}$ . (ii) Much of our work has been con-

cerned with SH groups, which, following theoretical suggestions of Heffter & Arnold, were the subject of extensive research by Gowland Hopkins (1921, 1929)<sup>25 26</sup>, who first isolated the SH compound—glutathione—which is present in the tissues, and demonstrated its properties; in particular, it may be noted that the characteristic purple reaction with sodium nitroprusside and ammonia is given not only by soluble substances in the tissues, but also by SH groups linked to insoluble proteins such as skin and boiled muscle-tissue, the so-called "fixed SH groups". (iii) Lastly, it should be made clear that chemical-warfare agents, in concentrations which are profoundly toxic to cells, are not general protoplasmic precipitants. Their action is much more subtle.

### 1. Biochemical Lesions and the Pyruvate-oxidase System

At least two events give rise to a blister of the skin: the initial biochemical lesion, and the more complex pathological response following in its train. The development of the antidote depended upon knowledge of the initial biochemical lesion<sup>c</sup>, and has been a curious mixture of planned and unplanned research. As much of the work involved the use of the pyruvate-oxidase system, it is appropriate to recall briefly some of our work upon the biochemical lesion in vitamin-B<sub>1</sub> deficiency<sup>33</sup>. By this term is meant the initial change in tissue-cells which precedes any damage visible with the microscope. For many years we studied in this connexion the condition of opisthotonus in the rice-fed pigeon due to vitamin-B<sub>1</sub> deficiency, a condition which is completely reversible in 30 minutes or less by appropriate injection of the vitamin (for review see references 40, 42). After ten years' work, it was proved (Banga, Ochoa & Peters, 1939)<sup>2</sup> that this convulsive condition is solely due to lack of the co-factor (aneurin- or thiamin-pyrophosphate)<sup>d</sup> in the brain-tissue, with a consequent interruption of carbohydrate degradation at the stage of pyruvate; energy-giving reactions therefore fail. Some of this research was used in the war-work.

Turning to a few details: the research rested upon the discovery of the specific action in vitro of vitamin B<sub>1</sub> upon the avitaminous brain in the presence of pyruvate ( $\text{CH}_3\text{CO}\cdot\text{COO}-$ ), or a pyruvate-yielding substrate; most of it involved observation of the respiration in vitro of mashed pigeon-brain tissue, called "brei", in which all outlines are destroyed, but nuclei remain mainly intact. The diagram (fig. 1) indicates the course of the reaction for brain-tissue respiring in vitro in lactate solutions of pH 7.35.

FIG. 1

In this reaction about two-thirds of the pyruvate is completely burned to  $\text{CO}_2 + \text{H}_2\text{O}$ ; the remainder is lost mainly by a side-reaction to acetate. Lack of aneurin-pyrophosphate interrupts the reactions at A, leading to accumulation of pyruvate in vitro<sup>48</sup>, and in vivo to large increases in the content of pyruvate in the blood in the final stage of the deficiency<sup>65</sup>. It is the only known biochemical difference between the brain of the convulsing pigeon and the normal brain.

### 2. Arsenical Researches

For proper perspective, it may be recalled that arsenicals were first used as toxic smokes in World War I; working under J. Barcroft, the writer well remembers the active research engendered by this, and at that time an attempt was made (McClelland & Peters, 1919)<sup>22</sup> to get some rules for the toxicity of such trivalent arsenicals to ciliates; in addition to the finding that aromatic compounds were more toxic than aliphatic, there emerged the important point that the oxides formed by hydrolysis were at least as toxic

<sup>a</sup> [BMB 1199]  
<sup>b</sup> L. Pauling has told the writer that he considers that the usually-accepted formula is not correct.

<sup>c</sup> A term introduced by Gavrilescu & Peters (1931)<sup>72</sup>.  
<sup>d</sup> Also called cocarboxylase.

as the corresponding chlorides. Arsenical compounds, after penetrating the skin as chlorides and hydrolyzing in contact with aqueous phases in the tissue, are still toxic, which is an important distinction from mustard-gas. About this time (1917) lewisite was discovered in the USA; as subsequent events showed, it was a highly significant substance.

Our researches in World War II for antidotes to the war gases were based upon two ideas: (i) that an SH group was attacked by the As<sup>e</sup> and (ii) that this was a constituent of the pyruvate-oxidase system. The work leading to these ideas will be briefly traced.

### SH Groups and Arsenicals

Following the work at Porton in World War I, the writer undertook fundamental investigations in the Chemical Defence field, and E. Walker came to help him. It was found that mustard-gas sulphone<sup>50</sup> stopped the glutathione catalysis of muscle-tissue just then described by Hopkins & Dixon (1922)<sup>27</sup>; as a fixed SH group is part of this system, there followed the finding that several vesicants abolished the reaction for this in muscle, skin and trachea, and that this occurred not only with the sulphone mentioned but also with diphenylchloroarsine and allyl isothiocyanate. At this stage we were much interested by the appearance of work upon therapeutic arsenicals by Voegtlin, Dyer & Leonard (1923)<sup>68</sup>, in which they showed that arsenoxide combined with glutathione in SH form, and that monothiol compounds in rather large excess protected against the toxicity of the arsenical. This led<sup>f</sup> to a test, with good effect, of the protective action of the monothiol thioglycolic acid and of monothioethylene glycol against diphenylchloroarsine in ciliates, and to some evidence for reversal of toxicity. Though convinced then of a connexion between the toxicity of these arsenicals and mustard-gas sulphone<sup>g</sup> and a combination with SH groups, a conviction also shared by Voegtlin (1925)<sup>67</sup> for the therapeutic arsenicals, our research was discontinued in 1926, largely owing to the lack of information as to the significance of the sulphur system.

Meanwhile, this connexion was strengthened by other work which was continued in relation to the therapeutic arsenicals, especially by Voegtlin's group and by Eagle (1939)<sup>16</sup>; Rosenthal (1932)<sup>54</sup> also found indirect evidence for the combination of arsenoxide with the SH groups of denatured albumen. During this time, also, it was shown (Cohen, King & Strangeways, 1931)<sup>8</sup> that thioarsinites were dissociated in alkaline solution, e.g. the equation  $RAsO + 2R'SH \rightleftharpoons RAs(SR')_2 + H_2O$  was reversible; an observation which we thought was a valuable pointer to the possibility of therapeutic reversal.

### Pyruvate-oxidase System and Arsenicals

The idea that chemical-warfare agents attacked cell-enzymes was early mooted<sup>20</sup>, though no proof was given, nor could we get evidence for this<sup>50</sup>. During the vitamin-B<sub>1</sub> researches, however, an observation was made which to the

writer<sup>40</sup> reopened the whole question of enzymes in relation to the problem. We had found (fig. 2) that

FIG. 2

iodoacetate interfered positively at A in a *normal* pigeon-brain brei in a similar way to the negative interference produced by vitamin-B<sub>1</sub> deficiency; both led to accumulation of pyruvate from lactate (Peters, Rydin & Thompson, 1935)<sup>44</sup>. The important fresh point was that small concentrations of mustard-gas sulphone ( $0.09 \times 10^{-3}M$ ) acted similarly; since other enzymes concerned in the brei (i.e. the cytochrome-system) were by inference unaffected, this experiment indicated a selective action of the poison upon the pyruvate-oxidase system. Iodoacetate is a weak vesicant; hence a causal connexion was suggested between the selective enzyme-attack and the biochemical lesion leading to vesication. About the same time, this was extended by the observation that minute amounts of arsenite (see reference 45) had a similar action<sup>h</sup>. The analogy with iodoacetate was especially interesting because work at that time in 1932-33<sup>11 62 63</sup> had led to the view that inhibitions produced by it were due to interaction with SH groups. Combined with the earlier observations upon arsenicals, it led to the suggestion that various poisons attacked an SH group in the pyruvate-oxidase system<sup>41</sup>.

Very early in World War II, after retesting some of these points, the writer felt prepared to initiate, defend and direct a programme of extramural research for the Ministry of Supply with the object of reaching antidotes for mustard-gas and lewisite based upon the two ideas presented above, and upon confidence in those around him in his laboratory. The matter is put this way intentionally; though biochemists have a natural faith in enzymes, and though we had then proof of the profound pathological effect of failure of cocarboxylase in vitamin-B<sub>1</sub> deficiency, the idea that toxic effects upon an enzyme could initiate such a complicated process as vesication was not then at all acceptable in physiological and medical circles, or in those of pure chemistry; nor was it thought likely that any poisoning could be reversed. One can well understand the hesitation felt, especially when in addition the reservation of personnel in war was in question.

The team who embarked upon this work were roughly divided so that at the start H. M. Sinclair & R. H. S. Thompson worked upon arsenical substances, and E. R. Holiday, A. G. Ogston, J. St.L. Philpot, L. A. Stocken & R. W. Wakelin upon mustard gas; but the work went forward as a whole, and there was constant discussion by all of the research group. After some ten months, Sinclair and Philpot left for other work; but later V. P. Whittaker and G. H. Spray joined.

It was soon confirmed that, among several enzymes examined, the pyruvate-oxidase system was by far the most

<sup>e</sup> A nitrogen group could not be absolutely excluded at that time, but was thought unlikely.

<sup>f</sup> Walker, E., 1925 (published 1928)<sup>70</sup>.

<sup>g</sup> Mustard-gas itself is an exception<sup>42</sup>.

<sup>h</sup> Krebs (1933) had previously claimed a specific effect upon  $\alpha$ -keto-acid oxidase; his concentrations of As were however too large to settle this<sup>43</sup>.

sensitive to lewisite and arsenite (Peters, Sinclair & Thompson, 1946)<sup>45</sup>. We also got more evidence for the presence of an essential SH group, because the enzyme system was inhibited by maleate and -S-S- compounds<sup>49</sup>. Both of these reagents had been introduced by Hopkins and his school<sup>28, 37</sup> for the detection of SH enzymes. Succinodihydrogenase is also present in brain brei and is an SH enzyme<sup>14</sup>; but it is less sensitive, so that at low concentrations of the arsenical, there is selective poisoning of the pyruvate-oxidase system<sup>1</sup>. Hence pyruvate should accumulate in the blood of an animal poisoned with these arsenicals, as happens in vitamin-B<sub>1</sub> deficiency. Table I shows that there is an increased concentration in the blood after poisoning with As.

TABLE I. EFFECT OF INJECTED ARSENITE ON THE BLOOD-PYRUVATE LEVEL OF PIGEONS

(Expressed as mg. pyruvic acid/100 g. blood, as determined by 2,4-dinitrophenylhydrazine method. Duration of intoxication given in parentheses.)

Normal	Acute	Chronic	Total dose As <sub>2</sub> O <sub>3</sub> (mg.)
1.28	4.02 (2 hr.)	12.39 (4 days)	8.5
0.94	3.00 (2 hr.)	14.15 (4 days)	8.5
0.94	3.12 (2 hr.)	13.85 (43 days)	7
	6.30 (3 hr.)		
Average	1.06	4.11	13.47

Similar results were obtained for bisulphite-binding capacity (B.B.S.) of the blood in pigeons, and for pyruvate and B.B.S. with arsenite and lewisite in rats.

Data of Peters, Sinclair & Thompson, 1946<sup>45</sup>

This formed the background for the use of the pyruvate-oxidase system as an enzyme for in vitro tests of arsenical antidotes, and it has never failed. Evidence was also produced (Thompson, 1946)<sup>43</sup> that pyruvate oxidation in skin was inhibited by lewisite. Nevertheless, at this stage there were still facts difficult to fit with the main ideas; perhaps the most serious of these was the complete failure to protect animals or even the brain-enzymes against the toxicity of these arsenicals (Sinclair, 1940)<sup>65</sup> by large concentrations of monothiols, a somewhat different finding from that of the Voegtlin school for arsenoxide. In the early summer of 1940, the war-situation was more serious; this meant a sharpened scepticism as to the value of enzyme research as a contribution to the war-effort, which finally led to the official discontinuance of the enzyme work; nevertheless the arsenical research was continued upon the basis of looking for possible specific antibodies to arsenical proteins which might be formed by lewisite<sup>1</sup>. It should be realized that during all this year thiol-compounds were being made (mainly by L. A. Stocken) in relation to the mustard-gas work; though the more obvious avenues in the arsenical work were now narrowing, there was still left the systematic study of the relative dissociation of various thioarsenites, often urged by Philpot; however the crucial experiment came differently. In connexion with the research into the arsenical "immune proteins", our colleagues Stocken &

Thompson (1946a)<sup>59</sup> started to make, and analyze for As-content, arsenical compounds of keratine (Goddard & Michaelis, 1934)<sup>22</sup>, which is a reduced keratin, rich in SH groups. For lewisite-keratine compounds made under biological conditions of pH and at room-temperature, it was found that from lewisite the amount of arsenic taken up in combination was limited; it was not increased by exposure to a considerable excess, and in great part the amount combined was conditioned by the presence of

TABLE II. ANALYSIS OF ARSENIC DERIVATIONS OF KERATEINE AFTER EXPOSURE TO EXCESS OF THE ARSENICAL

Data of Stocken & Thompson, 1946a<sup>59</sup>

-SH groups as such. With metakeratin, in which the SH groups have been oxidized to SS, the amount of As combined is no more than that from arsenate—about 0.05%. The lewisite-keratine was resistant to reprecipitation and dialysis. Most important of all, more -SH groups disappeared than As atoms bound by the keratine; from this, there followed the conclusion that some 75% of As must be bound in ring form with the protein SH. Since ring compounds would be expected to be a more stable combination, there emerged the "dithiol" theory (Stocken & Thompson), according to which the special stability of this enzyme "thio-arsenite" was due to the presence of two -SH groups upon a component of the enzyme so placed that a ring could be formed with a trivalent arsenical. It could be surmised that if a suitable dithiol could be found, able to form a more stable compound, as in fig. 3, it would

FIG. 3

reverse the combination with the tissue-protein. After preliminary trial of two dithiols, the new compound 2:3-dimercaptopropanol was synthesized (Stocken, 1947)<sup>61</sup>; ultimately this was called BAL (British Anti-Lewisite) by the workers in the USA—a courteous gesture; so nearly allied to glycerol, this substance has excellent penetrant properties for skin.

<sup>1</sup> It is interesting to note that the total oxidase-system is more sensitive to arsenite than the pyruvate-dehydrogenase component.

<sup>2</sup> All credit should be given to Mr. J. Davidson Pratt (and the Ministry concerned) for taking the responsibility of active support at this stage.

Synthesis of 2:3-dimercaptopropanol (BAL)

It is indeed a curious coincidence that the first new compound<sup>k</sup> made should be so efficient and also the least toxic in this series. Several dithiol compounds were subsequently made in Oxford and in Canada<sup>74</sup> and a large number in the USA<sup>71</sup>; none proved less toxic. The LD<sub>50</sub> (dose killing 50 % of a given batch) for rats is about 120 mg./kg.

The behaviour of BAL will now be briefly described. The compound lewisite-BAL is so stable that it gives no nitroprusside reaction. When added to a brain brei before addition of lewisite, BAL protects the pyruvate-system (Table III), in marked contrast to the monothiol compound.

TABLE III. BRAIN PYRUVATE-OXIDASE (BREI) AS TEST-SYSTEM FOR ARSENICAL ANTIDOTES (PROTECTIVE ACTION OF DITHIOLS)

The thiol was added immediately before the lewisite. The effects in successive respiration-periods are given separately.

Data of Stocken & Thompson (1946b)<sup>60</sup>

According to the theory outlined in fig. 3, it should also reverse the toxicity when established. Fig. 4 shows that this takes place, and adds the further points of interest that the reversal is not instantaneous and that delay in adding the antidote may lead to some irreversible damage.

Turning now to the effect upon skin in vivo, the photographs (fig. 5-6) show the antidotal action in man. Fig. 5 was taken 2 hours after applications of 1 mm. drops of lewisite at A, B and C. The right arm was treated with antigas ointment after 5 minutes at A, and after 2 hours at C; the left arm was treated with BAL at corresponding times; B was the untreated control. Fig. 6, taken 24 hours after contamination, shows that antigas ointment and BAL were equally effective after 5 minutes, but that after 2 hours only BAL prevented the blister. Indeed at 2 hours after contamination, there is usually erythema and often commencing oedema. The condition is reversed by the antidote and not by a monothiol compound. Remarkable

<sup>k</sup> Independently another preparation of this compound was later published.<sup>75</sup>

FIG. 4. REVERSAL OF TOXICITY TO PYRUVATE OXIDASE

Reversal by BAL of toxicity to the pyruvate-oxidase system induced by addition of sufficient lewisite to give 50 % inhibition of the respiration (approximately 17  $\mu\text{M}$ ). (From data of Stocken & Thompson, 1946b)<sup>60</sup>

also was the action upon the eyes (Mann & Pirie, 1941)<sup>34, 35</sup>; BAL in a strength of 5-10 % is the only compound able to save an eye when applied up to 10 minutes after contamination with an arsenical. A further "supporting" programme of work showed that, as was hoped, BAL eliminated arsenic from the skin after inunction of lewisite, with an accompanying increased excretion in the urine<sup>61</sup>. When injected into animals poisoned with arsenicals, it could save them even after such signs as diarrhoea had developed. The above experimental work in vitro and in vivo is excellent support for the dithiol theory.

The therapeutic applications of BAL in patients suffering from the accidents of arsenical therapy with therapeutic arsenicals, and from mercurial poisoning, are described elsewhere<sup>1</sup> (Thompson, 1947)<sup>64</sup>, and are a fortunate dividend from the war-research. The exfoliative dermatitis in patients is most probably due to penetration of traces of arsenoxide (otherwise called mapharside) into the skin. Some points about this are interesting. In a brain brei, more mapharside is needed for a given degree of poisoning, and more BAL to reverse the combination<sup>62</sup>; similarly extra BAL is needed to treat mapharside poisoning in vivo<sup>63</sup>; this is interpreted to mean that mapharside-BAL is more dissociated than lewisite-BAL. With mercury there is again a difference; though BAL is more efficient, some monothiols also show some activity.

### 3. Further Theoretical Points

The As-dithiol compound in the tissues is slightly more dissociable than the As-BAL, and it seems certain that the ring formed with the protein was larger than one of 5 atoms. Some attempt has been made (Whittaker, 1947)<sup>73</sup> to throw light upon this by comparing the therapeutic efficiency in the brain-test in vitro of dithiols of constitution  $\text{HS}(\text{CH}_2)_n\text{SH}$ , where the number of  $\text{CH}_2$  groups ranged from 2 to 12. The least-successful antidote was 1 : 4-butane dithiol ( $\text{SH}(\text{CH}_2)_4\text{SH}$ ); with this, As would make a ring of 7 atoms, which in the case of other compounds has been considered by organic chemists such as Ruzicka to be a less-stable configuration. It was estimated that the stability of the As-protein in the enzyme lay between that of an eight- and a fourteen-membered ring.

The problem of the toxicity of dithiol upon injection is independently interesting and does not appear to be entirely due to the increase produced in circulating SH groups. Webb & van Heyningen (1947)<sup>72</sup> of Dixon's team found

that BAL markedly inhibited metal-containing enzymes (cf. also Barron, Miller & Meyer, 1947)<sup>6</sup>.

Some two years after the introduction of BAL, a fresh development took place at Cambridge. Danielli & Mitchell, who had been working in Dixon's team upon problems of permeability in relation to the war-gases, with Owen & Shaw<sup>10 m</sup> introduced a BAL-glucoside (BAL-Intrav). This was specifically designed for the systemic treatment of lewisite-poisoning, and to be a highly water-soluble substance, which would remain in the tissue-fluids and not penetrate cells, and would consequently be less toxic. This compound fulfils some of its promise in animals, and it is hoped that further research will make it available for clinical tests. When injected into human subjects, the glucoside increased excretion of copper and zinc in the urine (McCance & Widdowson, 1946)<sup>32</sup>.

Little has been said about the work of others; after the initial work in Oxford and the acceptance of the value of

<sup>m</sup> Of the Imperial College of Science, London.

BAL at Porton, further research developed both there, in Cambridge<sup>15</sup> and at Edinburgh<sup>31</sup>. Some applications have been found in experimental arsine poisoning<sup>19, 30</sup>. Simultaneously, the valuable researches in the USA<sup>71</sup> and in Canada<sup>74</sup> included much work upon the essential problems of the composition of ointments, the pharmacology of BAL, and other therapeutic developments.

#### 4. General Implications

It is satisfactory that these researches carried out originally for a war-objective have repercussions in branches of science related to biochemistry. For pathology it is believed to be the first instance in which commencing damage in tissues can be reversed by a logical chemical step. We now have evidence that biochemical lesions in the oxidation stage of pyruvate can be due either to a vitamin-deficiency or to positive exposure to a toxic agent; in this sense the "enzyme" theory has grown up, though the writer would not suggest that this is the only mode of inducing cell-damage. Doubtless further research will show the importance of other enzymes along these lines; meanwhile, it can be noted that there is an especial delicacy about pyruvate oxidation, because it has been claimed that the same enzyme is also damaged in oxygen-poisoning<sup>4, 12, 57, 18, 35</sup> and in narcosis<sup>51</sup>.

Some pharmacological aspects of arsenic problems are now much more clear; but, in view of the complications of biology as well as of the chemistry of arsenic, it would not be suggested that all problems in the field of arsenical toxicity and arsenotherapy are now solved<sup>7</sup>. Many of the difficulties to be met in the application of Ehrlich's chemoreceptor theories have been well presented earlier (Dale, 1923)<sup>9</sup> and are still real today; there may be mentioned as an example the selectivity of the arsenical for the protozoal tissue. Nevertheless, the application of chemistry to the cell must always be revealing when based upon a proper physiology; Ehrlich's determination (1909)<sup>17</sup> to apply chemistry boldly to the cell is highly stimulating, when given a modern dress; his suggestion that the arsenoreceptor might be hydroxyl (to which he gave most stress) or sulphhydryl (based upon Heffter) is interesting, though not based upon experiment. When Voegtlin (1925)<sup>67</sup> later advanced the sulphhydryl group as receptor, this was based upon their work with thiol substances and arsenoxide. It is a fundamental advance upon this to be able to indicate the enzyme-protein constituent attacked and the mode of attack. Short of direct evidence by isolation, it is virtually

proven that the enzyme compound has an essential thiol group, and that with primary trivalent arsenicals the thiol groups are sufficiently contiguous to allow of ring formation.

During the last decade, a tribute to the inspiration of Hopkins, much work has been done upon SH enzymes<sup>28, 14, 24, 7</sup> as well as upon SH groups in other proteins<sup>66, 36</sup>; such SH enzymes require an SH group for activity. It has been learnt that such groups are not all equally activated for various inhibitors; for instance, triose-phosphate dehydrogenase is much more sensitive to iodoacetate than is succinodehydrogenase<sup>13</sup>. Hence there are possibilities of variation in activation as well as in spatial relation. Biochemical analysis has shown wide variations also for various trivalent arsenical compounds in the toxic inhibitions of different enzymes<sup>23, 5</sup> and their response to thiols; many instances of reactivation by monothiols were found. Dixon<sup>15</sup> and his Cambridge team during the war developed the theory that vesicants attack hexokinase, the enzyme responsible for the first stage in glucose-degradation; this was based mainly upon an interesting correlation in the toxicity of various vesicants and hexokinase inhibition. To this, lewisite must be an exception; though it poisons hexokinase, the inhibition in vitro is reversed by a monothiol, whereas in vivo (as for pyruvate oxidase) a "dithiol" is necessary<sup>9</sup>. Presumably in cases where the toxicity of an arsenical can be reversed by a monothiol, circulating glutathione will act as a natural antidote.

During the war, independently, in Belgium, Bacq (1946, 1947)<sup>12</sup> became interested in the relation between toxicity of chemical-warfare substances and their behaviour with SH groups; lately he has introduced the term "thioloprive substances". This generalization is useful, though it will be realized that the final detail of the biochemical action will vary.

In conclusion, it is the writer's opinion that the discovery of lewisite was of real significance for this progress, because the compounds formed with it are so non-dissociable that attention was diverted from monothiols. In this sense, it is particularly appropriate to point out how closely Britain and the USA have been associated in these developments. In fact this war-research as a whole, in its course and publication, in addition to its scientific interest, has set a shining example of the excellent standards which can be reached in international co-operation.

I wish to thank Miss J. Allen for secretarial assistance, Prof. R. H. S. Thompson for reading the MS and Dr. L. A. Stocken for help with diagrams.

<sup>9</sup> The dithiol theory applies only to arsenical action; whether 2 SH groups are needed for the activity of one enzyme molecule is a different problem.

### References

In the production of specific antidotes against the action of toxic agents inside the animal body, one of the main

objectives is to dissociate the toxic substance from the "tissue acceptor" with which it has combined, and to convert it by chemical reaction with the antidote into some stable derivative of lower toxicity, capable of excretion from the body.

As early as 1909 Ehrlich suggested on theoretical grounds that the "chemo-receptors" for arsenic in living cells might be hydroxyl or thiol groups, reaction with which would cause the metabolic disturbance characteristic of the toxic effect, and shortly after the 1914-18 war independent experimental evidence in support of this view began to accumulate (for a review of this work see Peters, 1947). Despite this knowledge, fundamental to a rational solution of the problem, no satisfactory specific therapy of arsenical intoxication had been evolved, although a number of different thiol compounds had been investigated in the hope that they might compete effectively with the tissue-thiols for the arsenic.

### I. Arsenical Vesicants

At the outbreak of the recent war, however, research into the production of arsenical antidotes was actively resumed in this laboratory, chiefly in respect of lewisite and the other arsenical vesicant "gases", and by 1941 an antidote that fulfilled many of the desired theoretical criteria had been produced (Peters, Stocken & Thompson, 1945). This compound was 2:3-dimercaptopropanol, subsequently called British Anti-Lewisite (BAL). Until the introduction of this substance the study of potential thiol antidotes

\* Information available on application to Ministry of Supply, London

against arsenic had been limited to the use of monothiol compounds. Towards the end of 1940, however, Stocken & Thompson, in the course of a quantitative study of the action of lewisite on the SH-protein keratine, isolated and analyzed the lewisite-protein compound, and showed that about 75 % of the arsenic contained in this derivative had combined in the ratio 1 As : 2 SH. This finding suggested at once the possibility that dithiol compounds might prove more effective than monothiols in antagonizing lewisite, a suggestion which was subsequently fully confirmed in animal and human experiments, no monothiol having yet been found which can prevent vesication by lewisite in man. 2:3-Dimercaptopropanol was synthesized and found to be the most suitable of a large number of dithiols prepared both in Britain and the USA.

This compound reacts with arsenoxides to give a five-membered-ring compound more stable than that formed between the arsenical and the "tissue-acceptor", and very much more stable than the compound formed between arsenicals and monothiols (Stocken & Thompson, 1946a, 1946b).

BAL is a colourless oil, approximately 6 % soluble in water at room-temperature; it is stable in the pure state, or when dissolved in non-aqueous media, but is rapidly oxidized in aqueous solution near the neutral point. Laboratory animals contaminated or injected with lethal amounts of lewisite can be effectively treated by the use of BAL applied either on the skin or by injection, a significant increase in the urinary excretion of arsenic resulting (Stocken & Thompson, 1946c). The blistering effect of lewisite on human skin can be prevented by the local application of BAL to the affected area as late as 1½ hours after contamination. This fact in itself provides evidence of the ability of BAL to reverse the toxic action of lewisite, since its application to the contaminated area can be delayed until after intense erythema has appeared; instead of progressing to the usual tense vesicle overlying an area of necrosis, the erythema in most cases disappears almost completely within 24 hours of the treatment.

Apart from these experimental results, BAL was used successfully during the war years for the treatment of accidental splashes of arsenical vesicants on the skin of factory-workers. Cases of accidental contamination of human eyes with arsenical vesicants were fortunately few, but the reports received indicated that those treated with BAL supported the general results of animal experiments, in which it had been found that the instillation into the conjunctival sac of a 5 % or 10 % solution of BAL within 5 minutes of contamination resulted in almost complete recovery.

The importance of determining the efficacy of BAL against the toxic effects of the therapeutic arsenicals was early realized, and in 1942 work was begun with this end in view both in Britain and the USA. In Oxford, Stocken, Thompson & Whittaker (1947) showed that BAL can protect the pyruvate-oxidase enzyme-system of brain against mapharside, neoarsphenamine and arsphenamine, and is

also effective in maintaining the survival of rats after the injection of lethal doses of mapharside or neoarsphenamine. In America, Eagle in 1943 demonstrated that BAL can resuscitate micro-organisms poisoned by mapharside, and is also of value in the treatment of acute or subacute mapharside poisoning in rabbits (Eagle, Magnuson & Fleischman, 1946); in the course of this work these investigators found that solutions of BAL in arachis oil containing benzyl benzoate could be sterilized by heat with only slight loss in activity.

Before this finding, work had been started on the treatment of arsenical dermatitis in man by the inunction of BAL ointments (Longcope, Luetscher, Wintrobe & Jager, 1946; Carleton, Peters, Stocken, Thompson, Williams, Storey, Levvy & Chance, 1946), but although distinctly encouraging results had been obtained, the irritant action of BAL on human skin, more pronounced on skin already inflamed, indicated that inunction was not an entirely satisfactory method of administration. Eagle's finding therefore was an important advance, since ampoules of the compound suitable for intramuscular injection into man could be readily prepared. In Britain, the ampoules finally used, prepared by a modification of Eagle's method, contained 5 % BAL in arachis oil and benzyl benzoate, the ampoules being nitrogen-filled and sterilized by heating for 1 hour at 170°C.

The treatment of a number of different metal-intoxications with BAL has now been investigated, and will be considered under the following headings.

## 2. Arsenical Dermatitis

### a. Dermatitis due to diphenylamine chloroarsine (phenarsazine chloride)

The first application of BAL to the treatment of widespread arsenical lesions in man was carried out by Longcope, Luetscher, Wintrobe & Jager (1946) in 7 cases of dermatitis occurring in workers exposed to the dust of diphenylamine chloroarsine (also known as DM). The lesions involved the exposed areas of the face, neck and arms, and had proved intractable to the standard forms of treatment, having been present, in 6 of the patients, for from 18 to 50 days before admission to hospital. Treatment with daily applications of BAL ointment caused the dermatitis to clear completely in from 2 to 8 days, with an average of a little over 5 days. In the course of this work it was shown that successful results could be obtained by inunction of the ointment into areas of normal skin, the BAL, after absorption, bringing about detoxication in the affected areas; by this means it was possible to avoid the intense burning sensation produced by the application of BAL to erythematous skin.

### b. Exfoliative dermatitis

Considerable experience has now been accumulated in the treatment of exfoliative dermatitis occurring as a complication of arsenotherapy. In a first series of 30 patients Carleton *et al.* (1946) have reported a beneficial effect in approximately 50 % of cases; 21 of these were treated by intramuscular injection, and the remainder by inunction.

In a more recent report (Carleton, Peters & Thompson, 1948) the results obtained in a further 44 cases have been described. Of these cases 41 were of the acute exfoliative type, and the dermatitis was in all cases severe and wide-

spread. The BAL was given by deep intramuscular injection into the gluteal region, the following course of injections being given in most cases :

First day : 4 injections of 2 ml. 5 % BAL at 4-hourly intervals ;

2nd, 3rd and 4th days : 2 ml. twice daily ;

5th and 6th days : 2 ml. daily.

From the reports received from the clinicians who co-operated in this trial, it has been concluded that a "good" response was obtained in 23 cases (52 %), while if 8 further cases in which a "fair" response was obtained are included, the number of those benefited by the treatment is 31 (70 %). In some cases an almost dramatic response was obtained, and the mean duration from the first injection of BAL to healing or nearly complete healing was 21 days. Photographs of one of the cases described in that report are given in fig. 1 and 2.

In America, Longcope *et al.* (1946) have described 15 cases of generalized exfoliative dermatitis following the use of anti-syphilitic arsenical drugs, and have stated that symptomatic and objective improvement regularly followed the administration of BAL. Luetscher, Eagle, Longcope & Watson (1946) have, in addition, followed the arsenical excretion in 16 cases and have shown that, in a proportion, BAL-therapy causes an increased elimination of arsenic in the urine. Carleton *et al.* (1946) also studied the urinary arsenic-level in a number of cases, but were unable to detect any significant increase following treatment with BAL. The absolute amounts of arsenic appearing in the urine are, however, small, and owing to the variations in the day-to-day excretion and to the long intervals which in some cases elapsed between the last injection of arsenic and the beginning of treatment, this result is not surprising.

The American workers, however, have used 10 % solutions of BAL and in severe cases have given a higher dosage than that used in Britain.

In several instances, clinical evidence of relapse has been obtained shortly after the end of BAL therapy. This has in every case responded satisfactorily to a further short course of injections.

#### *c. Arsenical hyperkeratosis*

An account of one case of arsenical hyperkeratosis of the palms and soles, together with marked pigmentation of the lower trunk and thighs, has also been received. This patient was given 2 courses of BAL therapy at an interval of a month. It was concluded that a definite reduction of the keratosis occurred in response to the treatment, accompanied by an almost complete disappearance of pigmentation. Although this is the only report of such a case, it is of interest in view of the chronic nature of this type of lesion.

### 3. Arsenical Encephalopathy

In a report of the Council on Pharmacy and Chemistry of the American Medical Association (1946) a brief account is given of the use of BAL in the treatment of 55 cases of "haemorrhagic encephalitis" caused by intensive arsenotherapy. Eleven deaths occurred in this series, but the remaining 44 patients recovered completely in 1 to 7 days. In 5 of the 11 fatal cases BAL was not injected until from 9 to 72 hours after the onset of convulsions or coma.

In Britain, BAL has been given in 3 cases. In 2 of these complete recovery took place in less than 1 week, while in the third, consciousness was recovered on the fourth day and an uninterrupted recovery with no residual sequelae followed.

### 4. Arsenical Granulocytopenia

Although the number of cases so far studied is small, BAL also appears to be of value in the treatment of granulocytopenia occurring during arsenotherapy. A favourable response in the leucocyte-count, with a proportionately greater increase in the number of polymorphonuclear leucocytes, occurred in 10 of 11 cases reported in the USA (Council on Pharmacy and Chemistry, 1946). Five cases have also been treated with BAL in Britain ; in each case a rapid restoration of the leucocyte-count occurred.

### 5. Mercurial Poisoning

Preliminary work on enzyme-systems and on laboratory-animals (Gilman, Allen, Phillips & St. John, 1946 ; Thompson & Whittaker, 1947 ; Stocken, 1947) has shown that BAL can also detoxicate mercury. An interesting series of 23 cases of acute poisoning by mercuric chloride in man, treated with intramuscular injections of BAL, has been described by Longcope & Luetscher (1946). The amounts of mercury swallowed by these patients varied from 0.5 to 20 g. of mercuric chloride. 22 of the 23 patients recovered completely, the one death being in a patient who was not treated with BAL until 13 hours after taking the mercury.

### 6. Gold Dermatitis

In 1945, experiments with the pyruvate-oxidase system of brain (Thompson & Whittaker, 1947) indicated that BAL might be of value in the therapy of gold-intoxication, and clinical reports have now appeared supporting this view. Cohen, Goldman & Dubbs (1947) and Ragan & Boots (1947) have described beneficial effects in the treatment of gold dermatitis, and the latter workers have also claimed that a significant increase in the excretion of gold in the urine accompanied the treatment. A few cases have also been studied in Britain with encouraging results.

Lockie, Norcross & George (1947) have also reported a case of thrombocytopenic purpura and another of granulocytopenia due to gold, both of which responded promptly to treatment with BAL.

### 7. Other Metal-Intoxications

Studies of therapeutic possibilities in connexion with other metals are still in an early stage. Barron & Kalnitsky (1947), using the succinoxidase enzyme-system, have shown that BAL and certain derivatives of BAL are effective in protecting this enzyme from the toxic effects of a number of metals including lead, antimony, bismuth, cadmium and zinc. Braun, Lusky & Calvery (1946) have examined the effectiveness of BAL in a number of different metal-intoxications in rabbits. It appears to be an effective antidote in acute poisoning caused by antimony, bismuth, chromium, nickel and mercury, but is ineffective against lead, thallium and selenium ; in the case of lead and selenium, indeed, BAL appeared to produce an additive toxicity. Its use in experimental cadmium-poisoning has

FIG. 1. ARSENICAL DERMATITIS BEFORE TREATMENT

The photographs show the condition on the day (14/6/46) of commencement of treatment with BAL

FIG. 2. ARSENICAL DERMATITIS AFTER TREATMENT WITH BAL

*By permission of the Editors of the Quarterly Journal of Medicine*

The photographs show the same case as in fig. 1, 14 days later

been studied extensively, but although it has proved of value in protecting animals from the systemic effects of this metal, it appeared to form toxic complexes with the cadmium which gave rise to serious renal damage (Gilman, Philips, Allen & Koelle, 1946; Tobias, Lushbaugh, Patt, Postel, Swift & Gerard, 1946).

The toxicity of BAL to man has been the subject of careful study in America (Sulzberger, Baer & Kanof, 1946; Modell, Gold & McKen Cattell, 1946). In brief, it has been shown that the minimal dose given by intramuscular injection which causes toxic reactions in man lies between 3 and 5 mg./kg. Single doses of up to 8 mg./kg. have been given, and even at this level the toxic manifestations are completely reversible, lasting only about an hour or two. Apart from subjective phenomena, lachrymation, salivation, vomiting and an elevation of both systolic and diastolic blood-pressure occurred with these higher doses. It should be pointed out again that the therapeutic dose used in Britain is only about 1.5 mg./kg. bodyweight.

In Britain, Cameron, Burgess & Trenwith (1947) have studied the toxicity of BAL to rabbits with experimentally-

induced renal and hepatic damage. No evidence was obtained of any increased toxicity in animals with renal damage, except when renal failure was complete or nearly complete, when a slight lowering of tolerance to BAL was observed. Evidence of increased toxic effects was, however, present in animals with hepatic damage, suggesting that care should be exercised in the administration of BAL to patients with impaired liver-function.

An important water-soluble derivative of BAL, BAL-Intrav, has also been prepared in Britain (Danielli, Danielli, Mitchell, Owen & Shaw, 1946). It is a glucoside of BAL, and is of strikingly low toxicity. It has been shown to be of distinct value in the treatment of animals poisoned with large doses of lewisite, but, except for experimental purposes, has not yet been obtained in a form suitable for injection into man.

#### ACKNOWLEDGEMENTS

My thanks are due to Dr. T. E. Anderson for permission to mention his case of arsenical hyperkeratosis, and to Dr. A. B. Carleton for the photographs of her case of exfoliative dermatitis in the Radcliffe Infirmary, Oxford.

- 1 Methods of biochemical genetics
  - 2 Difficulties and advantages of man as a subject for chemical genetics
  - 3 Prospects of human chemical genetics
  - 4 Non-genetic heredity
  - 5 Future progress
- References

The study of biochemical reactions influenced in vivo by genes, or conversely the study of genes that control biochemical processes in vivo, is the subject-matter of biochemical genetics. Since the general acceptance of Mendel's principles after their rediscovery in 1900, it has seemed likely that many genes exert their influence by affecting the course of chemical reactions in the organism. This influence may be direct or indirect. The primary action of a particular gene may be concerned, for example, with the synthesis of a coenzyme. A mutation of this gene to an inactive form, followed by the production of an organism homozygous for it, would result in an organism in which a number of reactions dependent on coenzyme would now be impossible and in the organism being viable only in the presence of external sources of coenzyme. Thus, it might appear that mutation of a single gene was responsible for the failure of several reactions (secondary effects), though the immediate effect is the failure of one reaction only (primary effect). It may be argued that the chain of events could be followed further back—that the mutation might be responsible for failure to synthesize not a coenzyme, but an enzyme responsible for coenzyme-synthesis, or even an enzyme-precursor of the enzyme responsible for coenzyme-synthesis. At present, however, it can be said that some genes have definite effects, among which can sometimes be found a primary effect that is connected with a definite biochemical reaction. The hypothesis that genes act by means of their control of biochemical reactions, that there is a "one gene, one reaction" relation, and that where a gene appears to have other effects (such as psychical or morphological) these will be found to be consequent on biochemical effects, seems likely to be a fruitful stimulus to further work.

The first demonstration that such gene-controlled reactions occur was made by Garrod in his pioneering work *Inborn errors of metabolism* (1909). Garrod discussed fully the biochemical and genetic

aspects of alcaptonuria and laid the foundations of the study of biochemical genetics. In 1914, Gross discovered an enzyme present in the serum of normal individuals, and absent from the sera of alcaptonurics, capable of catalyzing the oxidation of homo-gentisic acid. This enabled Garrod, in the second edition of his book in 1923, to complete the demonstration that alcaptonuria was due to the absence of a gene responsible for producing an enzyme catalyzing a relatively-simple biochemical reaction; but his work was almost completely ignored by geneticists until its significance was emphasized in recent years, notably by Haldane.

Since that time, only one other chemical reaction controlled genetically, in which *both initial and final products* of the reaction are of known composition, has been discovered in man. In this, the absence or inactivity of the gene results in the appearance of phenylpyruvic acid in the urine. This condition, discovered by Folling in 1934, was subsequently thoroughly investigated in Britain by Penrose (Penrose, 1935; Penrose & Quastel, 1937). Like alcaptonuria, the condition is inherited as a recessive character, and appears to be due to the absence in affected subjects of a gene controlling, in some way, the ability to oxidize phenylpyruvic acid to *p*-hydroxyphenylpyruvic acid. A single case of a related biochemical disability has been noted in a subject unable to oxidize the latter compound to the 2:5-dihydroxy compound (Medes, 1932). Since only one case has been studied, it has not been possible to show that this condition, too, is inherited as a recessive, though there is every reason to believe that it is. A summary of these genetically-controlled disabilities in the oxidation of phenylalanine and related compounds is reproduced as fig. 1 (after Haldane, 1941). Other hereditary peculiarities of metabolism in man that appear likely to have a relatively-simple

FIG. 1. PHENYLALANINE-TYROSINE METABOLISM IN MAN (BASED ON HALDANE, 1941)

biochemical cause of the type responsible for alcaptonuria and phenylketonuria, are congenital steatorrhea, pentosuria, cystinuria and haematoporphyrin.

Hair- and skin-colour in man is due to the presence or absence of melanins. The melanins are complex substances whose composition is obscure, and their study is made more difficult by the facts that they are insoluble and the degree of physical dispersion may cause variations in their colour, though not necessarily in their composition. The inheritance of coat-colour in the guinea-pig has been intensively studied by Wright (1941), who has shown that at least seven genes are involved, some of which are concerned with pigment-synthesis and some with follicle-differentiation. Non-genic agents may also be involved (Billingham & Medawar, 1947). Owing to the number of genes involved, and the complex nature of their end-products and interactions, it seems unlikely that an understanding of the inheritance of pigmentation, and the characterization of the reactions involved, will soon be achieved for man.

### 1. Methods of Biochemical Genetics

Until recently, biochemical genetics has been concerned with defects of metabolism that are not usually of prime importance to the organism. That this is so, follows from the fact that only those defects are open to observation which are not sufficiently serious to kill the subject before its metabolism can be examined. A further limitation is imposed by the fact that the vast majority of mutations are recessive, and are therefore usually masked by the presence of a dominant allele whose influence can be eliminated only by breeding-experiments. Much fruitful recent work has been rendered possible by avoiding this difficulty by the use of organisms that can be investigated in the haploid stage. Among such organisms are some yeasts and moulds, *Saccharomyces* and *Neurospora* in particular. These organisms have the further advantage that the generation-time is short—6 days for *Saccharomyces*. The advantage of a short generation-time was of course realized early, and accounts largely for the intensive use of the fruit-fly *Drosophila* (generation 10 days) in genetical studies. Although bacteria, which have a short generation-time and are well suited to biochemical study, undergo changes apparently similar to mutation in higher organisms, they are not susceptible to genetical study as their reproduction is vegetative.

Although genically-controlled biochemical disabilities which would be lethal to the organism cannot be studied in most subjects, *Neurospora* has been used in this way (Beadle, 1945a). *Neurospora* is a mould that will normally grow well on a very simple medium containing only salts (including a nitrogen-source), an energy-source, such as a suitable fat or carbohydrate, and the vitamin biotin. Irradiation of *Neurospora* peritheca prior to reduction-division results in the production of ascospores which may contain mutant genes. On germination, these ascospores form a haploid mycelium which should show the effect of any mutations produced. Some of these mutations will be such that the organism is no longer able to synthesize all the compounds normally required in its metabolism. Such a spore would not therefore be capable of growth on a simple medium, and the mutation could be classed as lethal. If, however, the spores are allowed to germinate on a medium

containing as many substances, likely to be of importance in the mould's metabolism, as the investigator can supply, growth may occur. If transfer to the simple medium shows that such a mutation has occurred, the use of the medium supplemented singly with known compounds will reveal the particular failure in synthetic ability that has been induced. An examination of the mutants obtained in this way has added a great deal to our knowledge of chemical genetics. It has been shown, for example, that no less than 7 genes are concerned in the synthesis of the amino-acid arginine by *Neurospora* (Srb & Horowitz, 1944). Further analysis of these mutants has rendered it likely that each of these genes is concerned with a single stage of the synthesis (fig. 2).

### FIG. 2. ARGININE SYNTHESIS IN NEUROSPORA

Genes controlling steps in this scheme are identified by the numbers of the mutant strains in which they were first found (Srb & Horowitz, 1944).

NOTE: That two reactions were concerned in the transformation of ornithine to citrulline was suggested by Srb & Horowitz because two genes were necessary. It had been suggested earlier by Krebs (1936) that two reactions were likely to be involved:

Work on the biochemical genetics of *Saccharomyces* is of considerable theoretical importance, in that it has shown that changes in a gene may be obscured by cytoplasmic effects. A diploid yeast, heterozygous for the gene controlling the formation of an enzyme responsible for ability to ferment the sugar melibiose, will produce under normal circumstances four haploid ascospores of which only two will be capable of melibiose-fermentation on germination, owing to the segregation of the gene responsible. If, however, melibiose is present throughout copulation and ascospore-formation, the cultures derived from the four ascospores will all be able to ferment melibiose. Segregation of the gene responsible has occurred in the normal manner, however, for it can be shown that two of the cultures will lose permanently the ability to ferment melibiose if grown in its absence, while the other two do not. Thus, it must be concluded that the enzyme responsible, or a precursor, is capable of self-reproduction as long as its substrate is present. It is possible that, if this mechanism is shown to be of wide occurrence, it may prove that some enzymes acting on substrates invariably present in cells may no longer be produced under genic control, but may be perpetuated by a cytoplasmic mechanism.

As a result of work on haploid organism, no less than 9 of the total 25 genically-controlled reactions listed in the recent review by Beadle (1945b) have been discovered, and another 4 are accounted for by the work of Moewus on sex phenomena in *Chlamydomonas*. Thus, rather more than half the data of chemical genetics derives from the study of micro-organisms.

After micro-organisms, the most fruitful type of material quantitatively has been the higher plants, which account for a further seven reactions. These include those responsible for anthocyanin synthesis, glucoside hydrolysis, and a carotinoid transformation, and are not of great interest for the present purpose, though adding to the evidence that each step in a synthesis may be controlled by a single gene. A reaction involving an oxidation of tryptophan in insects, the hydrolysis of atropine in the rabbit, and the formation of allantoin from uric acid in dogs, completes the list of known reactions, with the addition of the two already described for man.

A consideration of the results so far described gives reason to believe that many of the metabolic processes of man will be found to be under genic control. The accumulation of knowledge related to metabolism in man may enable some conditions, found to be due to abnormal metabolism, to be controlled by supplying substances that cannot be synthesized, or by excluding from the diet substances whose abnormal metabolism may lead to disease. It may be argued that vitamin therapy is an example of this method, for there is no sharp distinction between the treatment of a *Neurospora*-mutant incapable of synthesizing thiamin, by supplying it in the culture-medium, and treating scurvy in man by ascorbic acid, which other mammals can synthesize, though man cannot.

## 2. Difficulties and Advantages of Man as a Subject for Chemical Genetics

The difficulties inherent in the study of the genetics of man have been summarized by Crew (1946), who points out that a

species which lives in an environment created by itself, and which is notable for its variety, must present considerable difficulties when the species itself reproduces so slowly, has so few offspring, fails to maintain pedigrees, and cannot be used as experimental material.

There are, however, advantages in the study of man. The population available for study is large, and the presence of abnormality of any kind in a large part of it is likely to be brought to the attention of medical men and through them to that of geneticists. The study of human genetics also widens the range of data available, since the subject can describe reactions to stimuli that would otherwise be hard to determine. It is a simple matter to examine human beings for colour-blindness, more difficult and time-consuming for bees or birds. The study of mental symptoms which may occur as end-effects of simple failures of metabolism (imbecility in phenylketonuria) is not only of great practical importance but almost impossible in other experimental material.

## 3. Prospects of Human Chemical Genetics

The possible applications of a fuller knowledge of biochemical genetics of man may be divided into :

- i. Avoidance of the full expression of deleterious genes.
- ii. Avoidance of deleterious consequences of gene-action.
- iii. The suppression of undesirable genes.

Many genes give rise, not to the invariable manifestation

of a character, but to a predisposition to a character that may be exhibited only after some stimulus, presumably environmental in origin. The absence of sweat-glands, for example, may not be noticed in the British climate, but transfer to the tropics makes it obvious. In other examples, the exciting factor that may cause the exhibition of symptoms of conditions hitherto latent is not known. Epileptics show a characteristic wave-pattern in electroencephalograms, and similar patterns occur in non-epileptic subjects who may be supposed to have inherited epileptic tendencies. Only about one in twenty of subjects with the epileptiform electroencephalogram is an epileptic, and present evidence indicates that the predisposition is inherited as a simple Mendelian dominant (Lennox, Gibbs & Gibbs, 1939). Further research may succeed in identifying the evocative conditions, and enable them to be avoided by those disposed to epilepsy.

Even if the action of a gene cannot be avoided, its ill effects may be circumvented. The occurrence of blood-group antigens is genically-controlled in man, and among them the rhesus series is of importance in the study of haemolytic disease of the newborn (Race, 1946).<sup>1</sup> While no example is known of antibodies to rhesus antigens occurring spontaneously, they are readily formed in response to immunization. This immunization may be due either to transfusion of blood containing rhesus antigens not present in the recipient's blood, or to the introduction of such antigens from the foetus into the circulation of the mother. The maternal rhesus antibodies formed in response to this iso-immunization may travel across the placenta, causing haemolysis in the foetus. Haemolytic disease of the newborn in those cases (the majority) due to the rhesus incompatibility between mother and child is, of course, determined genically, since the occurrence of the antigens responsible is genically determined. It is, however, another example of a condition that is shown in only a small number of the cases in which it might be expected. About one pregnancy in ten is such that the necessary antigen-distribution between mother and child is present, yet evidence of maternal antibody-formation is obtained in only about one in 250 pregnancies. It has been shown that some of those cases of haemolytic disease of the newborn not explicable on the basis of rhesus incompatibility may be due to incompatibility of the ABO groups—a condition hitherto unnoticed owing to the great rarity of the response in conditions apparently favourable (Aubert, Cochran & Ellis, 1945).

When haemolytic disease of the newborn does occur, it may vary in severity. Effects range from jaundice to kernicterus and hydrops foetalis. When the effects are limited to jaundice, cure is possible by transfusion of blood not haemolyzed by the antibodies present in the infant's plasma. Haemolytic disease of the newborn is thus a good example of a genically-controlled disease in which the primary gene-effect (antigen-formation) is intrinsically harmless but may lead to secondary effects of a varied and severe nature. It is also a genically-controlled disease that can be successfully treated in some cases. It is possible that, when the chemical structure of the hapten portion of the blood-group antigens is known, they may be synthesized and used in the treatment of the disease in utero, for it

<sup>1</sup>[B.M.B. 872]

might be possible by their use to keep the maternal antibody-level low enough to avoid significant transfer across the placenta.

The complete suppression of undesirable genes may be attempted in two ways. The first is that of controlled breeding, or eugenics, and will not be discussed. The second is selective mutation. Agents are known that may be used to increase the mutation-rate, but none is selective; they may be said to lead to increase in the spontaneous mutation-rate of all genes. Among these are a number of chemical compounds, one of which, allyl isothiocyanate, occurs naturally in some plants (Auerbach & Robson, 1944). Other far more effective compounds are mustard-gas and some related compounds (Auerbach & Robson, 1946). Mustard-gas is a very powerful agent indeed, giving as high a mutation-rate as x-rays. These agents are non-specific, but it is possible that the investigation of the nitrogen- and sulphur-mustard groups which already show some tissue selectivity (Gilman & Philips, 1946) may lead to the discovery of compounds with some selective action on mutation. The demonstration by Demerec (1947) that the carcinogen 1:2:5:6-dibenzanthracene is also mutagenic will lead to the investigation of some of the large number of known carcinogens, and the relation between carcinogenic and mutagenic power in these should prove to be of the greatest interest.

The possibility of inducing mutation in a particular gene has led to some experimental work that is unfortunately inconclusive at present. In 1920 Guyer & Smith claimed that they had induced heritable eye-defects in rabbits by the injection of antisera against eye-lens protein into pregnant rabbits. Attempts were made by other workers to confirm these results but were unsuccessful. Recently, however, Sturtevant (1944) has said that Hyde succeeded in confirming the work of Guyer & Smith just before his death in 1943. Sturtevant's interpretation of this finding is that there is a similarity in molecular shape of the gene and the antigen it produces. Thus, antibody may combine with the gene and interfere with its duplication in such a way that the genes produced are not effective in antigen-production. This is tantamount to the induction of specific mutation. Emerson (1944) attempted to induce similar mutations in *Neurospora* by treatment with antisera prepared against *Neurospora* mycelium or *Neurospora* culture-filtrates. The material used was a mixture of antigens, and presumably gave a very varied collection of antibodies. It was found that the mutation-rate of *Neurospora* was increased by antibody treatment, but this may well have been a non-specific effect, for no controls with normal sera were done and owing to the probably-mixed nature of the antibody used, specific effects would not have been easy to detect. In spite of the interest of this work it has not been repeated or confirmed. There seem to be a number of probable difficulties in bringing gene and antibody into contact, for it is necessary not only to move antibody across the cell-membrane but to maintain a sufficient concentration of it once there, in the presence of intracellular proteases that are likely to break up foreign proteins. It seems unlikely that such methods of specific mutation will become of practical interest in human genetics, more especially because they are likely to inactivate genes, rather than restore genes that have lost their function, and consequently are likely to be of value only in modifying dominant genes.

#### 4. Non-genetic Heredity

At present there is great interest in types of inheritance that involve cytoplasmic factors for which the name "plasmagenes" has been coined. It is supposed that, like genes, these are capable of self-duplication, and that they may have properties such as to constitute a link between virus and gene. In addition to the very considerable body of speculation on cytoplasmic inheritance, there is some definite evidence that it does occur. In plants, the plastids are known to be self-duplicating bodies, liable to sudden changes that are then perpetuated. Their duplications seem to be influenced to some extent by genes. The work of Lindegren (1945) on cytoplasmic inheritance of a sugar-splitting enzyme in *Saccharomyces* has already been discussed; other work emphasizing the close interrelations that exist between intra- and extra-nuclear inheritance is that of Sonneborn (1945) on the "killer" character of *Paramecium*. The demonstration that one of the factors responsible for mammary cancer in mice appears to be extra-nuclear and self-duplicating may lead to work on cytoplasmic inheritance in higher animals. This field is discussed more fully by Haddow (1947)<sup>2</sup>. It had long been apparent that many of the factors responsible for the production of an adult from a fertilized egg were cytoplasmic. All cells in the body have the same genic constitution, but they differ greatly from each other. That this difference is not merely one of environment is demonstrated by tissue-culture in which cells do not all revert to the same type, in spite of having the same environment. In tissue-cultures, at least four distinct types of cell which all have the same genic constitution are recognizable. It may be concluded then, that these differences are due to self-duplicating cytoplasmic factors. Studies of inheritance in bacteria and mutation-like changes in viruses, such as phage, may be relevant to cytoplasmic inheritance in higher organisms.

#### 5. Future Progress

Biochemical genetics is hampered at present by our lack of knowledge of the structure of most of the more-important constituents of the cell. It is commonly assumed that the genes are nucleoprotein in nature, but we know little of the fine structure of proteins and less of the structure of nucleic acids. One of the plant-viruses was shown to contain nucleic acid in 1936 (Bawden, Pirie, Bernal & Fankuchen), yet it was not until 1947 that it was shown that this nucleic acid had 3 mononucleotides of the same composition as 3 of the 4 mononucleotides of nucleic acid from yeast (Schwerdt & Loring, 1947). About the order in which the components of nucleic acids are arranged, nothing is known, though there is evidence from the extremely fine specificity of the type-determining nucleic acids responsible for pneumococcal-capsule synthesis, that order and arrangement in space of the components may be of the greatest importance in determining specificity. The work of Todd and his school in Britain gives ground for hope that the synthesis of simple nucleic acids is not very far off (Todd, 1946). In our knowledge of the structure of the proteins we are more advanced, but again little is known of the order of different amino-acids that make proteins. A third class of high-molecular-weight polymers is the polysaccharides.

## DEVELOPMENT OF IDEAS ON THE NATURE OF VIRUSES

N. W. PIRIE M.A.

*Rothamsted Experimental Station, Harpenden*

- 1 Size as a criterion
  - 2 The physico-chemical approach
  - 3 Microbes or molecules?
  - 4 Nature of the fundamental virus-particles
  - 5 Combination of virus with tissue-constituents
  - 6 Conclusions
- References

The idea that a disease can be contagious, that is, caused by direct or indirect contact with another case of the disease, is old. It appears in the Old Testament and the Decameron, to cite popular writing as evidence of a more or less general acceptance, and it was set out in a manner acceptable to scientists by Fracastorius (1546). Until bacteria had been recognized by the early microscopists no suggestions, based on evidence, were made about the nature of the infective agents. During this period the word virus was used indiscriminately to cover agents, such as snake-venoms, which cause pathological states that are not transmissible from one victim to another, and also infective agents. The restriction of the word to infective

agents came with Pasteur's unequivocal demonstration of the role of bacteria in causing disease, and it was then used for any infective material, whether an organism had been recognized in it or not. As an example of this broad use Pasteur may be quoted (1889); the translation by Ruffer is used because it appeared a year earlier than the French version of this article.

Moreover, it is not difficult to prove that rabies is a disease which cannot appear *de novo* under any physiological conditions, and that its spontaneous origin is quite impossible. We know nowadays that contagion or virulent affections are caused by small microscopic beings which are called microbes. The anthrax of cattle, malignant pustule of man, is produced by a microbe; croup is produced by a microbe . . . The microbe of rabies has not been isolated as yet, but judging by analogy, we must believe in its existence. To resume: every virus is a microbe. Although these beings are of infinite smallness, the conditions of their life and propagation are subject to the same general laws which regulate the birth and multiplication of the higher animal and vegetable beings.

On the strength of this and some other passages the suggestion that the agents causing certain diseases could be smaller than the visible bacteria is sometimes attributed to Pasteur. It is clear however that he wisely refrained from making any suggestion to explain his inability to find a rabies organism.

Ivanowski (1892) found that the sap from plants suffering from tobacco mosaic retained its infectivity after passage through a Chamberlain filter-candle but, being convinced that the disease was due to a bacterial infection, he argued that the symptoms might be due to bacteria penetrating the candle or to a toxin secreted by the bacteria. He could have disproved the latter suggestion by demonstrating that plants which showed symptoms as a result of inoculation with the filtrate had an infective sap, but he does not appear to have done so. This experiment was carried out with foot-and-mouth disease by Loeffler & Frosch (1898). They tried to make a vaccine by removing the infective particles from vesicle-lymph by passage through a filter-candle, but

## HUMAN BIOCHEMICAL GENETICS

*Continued from page 328*

Many antigens owe their specificity to the polysaccharide moiety of the whole, among them those of the blood-groups and those responsible for type-specificity of pneumococci. A study of the former compounds is being carried out by Morgan in Britain (Morgan, 1944).<sup>3</sup>

were surprised to find that the filtrate still produced symptoms of disease. Although well aware of the high dilution at which foot-and-mouth lymph is infective, they argued that the effect could not be due to a toxin because the lymph from animals that had been inoculated with a filtrate produced symptoms. As an alternative they suggested that the agent, although small enough to pass through the pores of the filter, multiplied in the affected animal. They also suggested that a group of other diseases might have a similar cause. In the same year, the significance of passage through a porcelain filter was also fully appreciated by Beijerinck (1898). He filtered tobacco-mosaic virus and also demonstrated the diffusion of the infective agent through agar gels. These experiments led him to suggest that the agent was not "corpuscular" but was what he called *contagium vivum fluidum*.

### 1. Size as a Criterion

It is not easy, at the present time, to understand what precise distinction, other than the purely quantitative one of particle-size, Beijerinck was making. Atomic theories were already 2,400 years old, and the atomic and molecular conception of matter had achieved general acceptance during the 19th century. The reality of atoms was, it is true, still doubted by Ostwald and other members of the "Energetics" school, but more perhaps as a logical exercise than as a matter of practice. Clerk Maxwell spoke confidently, in an article in the *Encyclopaedia Britannica* (1875), of their reality, and even made some estimates of the number of molecules in the smallest organisms and emphasized the bearing of this subject on current theories of heredity. However, as late as 1909, Perrin entitled his masterly survey of the various independent methods by which Avogadro's number could be determined "Mouvement brownien et réalité moléculaire". When Beijerinck wrote, the nature of matter was in doubt, and even those who believed in molecules were uncertain of their size. Biologists at that date may therefore be forgiven for imagining that a fundamental qualitative difference existed between the corpuscular or particulate and the soluble or fluid states of matter; there is less excuse for the traces of the same belief that still linger in the writings of some pathologists.

Filtration through a candle was established as a practically-useful, but arbitrary, upper size-limit to the group of viruses. This was at first expressed in the phrases "filtrable microbe" or "filtrable virus", but usage and the fact that diseases resembling the virus-diseases in other ways are sometimes not transmissible by filtrates, has led to the adoption of the simple word virus to cover this ill-defined group. There is no rigid boundary between the large viruses and the small bacteria, and a discussion on the correct category for an agent like that of pleuropneumonia might have value in law but has none in science. The lower limit of size is equally uncertain. The factors causing capsule-formation in rough strains of pneumococci are generally looked on as "substances" rather than viruses, but this distinction is not logical. Transformation is associated with the production of more of the factor, so that one has the phenomenon of multiplication of the factor in susceptible organisms. Avery, MacLeod & McCarty (1944) have evidence that transformation is due to a polymerized nucleic acid. The possibility of virus-like action

with simpler substances remains open. Plant-galls can be produced by treatment with auxins; if the gall were itself rich in auxin, the state of affairs would be formally indistinguishable from an infection. An extract of the anomalous tissue would produce more of the characteristic anomaly when put on to healthy susceptible tissue. No example of this phenomenon is yet known, but it may be confidently predicted that examples will be found and that the effective auxins will be synthesizable. There will then be a smooth gradation, without any qualitative break, from synthesizable molecules at one end to microscopically-visible organisms at the other.

### 2. The Physico-chemical Approach

In the first quarter of this century the problem had been defined, certain infective states were classified as virus-diseases, and limits could be put to the size of the effective agents. It was not immediately obvious that the nature of a virus was a suitable theme for biochemical investigation, because our knowledge of the sizes of other biologically-important colloids was still meagre. It is unlikely that anyone giving serious thought to the matter doubted that viruses contained protein, because the unique role of proteins in biological phenomena had long been accepted; but protein-sizes had not been measured. Some tentative figures were derived from the elementary composition of proteins, especially from the iron content of haemoglobin, but it was not until the decade 1920-30 that osmotic pressure and ultracentrifugal measurements gave figures of generally-accepted validity.

The narrowing of the gap between the larger proteins and the smaller viruses stimulated many workers to investigate viruses from a chemical or physico-chemical standpoint. Two early purifications, that of vaccinia virus by Craigie (1932) and of a *Bact. coli* virus by Schlesinger (1933, 1936), were outstandingly successful. These viruses lack the geometrical or electrical simplicity that is a prerequisite for crystallization or the exhibiting of other striking physical properties, but it is probable that the preparations made in 1932 contained as high a proportion of active virus in the original state as most virus-preparations that have been described since. They were certainly more fully entitled to the designation "pure virus" than any plant-virus preparation made before 1940. Several attempts to purify tobacco-mosaic virus were made. Barton-Wright & McBain (1933) tentatively identified it with a protein-free crystalline material that they made from infective plant-sap. This suggestion was received sceptically by biochemists. A more confident identification by Stanley (1935) was at first similarly received. This scepticism was fully justified, for all the novel properties ascribed by Stanley to his crystalline globulin have proved not to be properties associated with the virus. The properties that are now accepted as those of tobacco-mosaic virus in its aggregated state were set out by Bawden, Pirie, Bernal & Fankuchen (1936) and were more fully defined by Bawden & Pirie (1937a) and by Bernal & Fankuchen (1941). Stanley has, from time to time, incorporated these properties in his description of the virus. This promotes unanimity but leads to the impression that his early description was confirmed rather than contradicted. Some parts of the description, e.g., the formation of tactoids in strong neutral solution, and fibres or "para-

crystals" rather than true crystals on precipitation with acid or on salting out, were accepted by Stanley almost immediately. Other parts were accepted more slowly, e.g. the invariable presence of nucleic acid in active preparations (Loring & Stanley, 1937; Stanley & Loring, 1938), and then only after argument (Bawden & Pirie, 1937b). The properties found with these early preparations are those of aggregates (Bawden & Pirie, 1937a; 1938c; 1946); this very important point has not yet been accepted by Stanley. It will be referred to more fully later. The sap of plants infected with various other viruses has yielded characteristic nucleoproteins which are either the viruses or are related to them. Some of these resemble tobacco-mosaic virus in forming liquid crystals, e.g. potato X (Bawden & Pirie, 1938a) and potato Y (Bawden & Pirie, 1939); others form true three-dimensional crystals, e.g. bushy stunt (Bawden & Pirie, 1938b), tobacco necrosis (Pirie, Smith, Spooner & McClement, 1938; Bawden & Pirie, 1942) and turnip yellow mosaic (Markham & Smith, 1946).

### 3. Microbes or Molecules?

The preparation of so many plant-viruses in forms with characteristic chemical and physical properties has fostered two unfortunate illusions: that there is a qualitative distinction between plant- and animal-viruses and that plant-viruses have been shown to be substances or molecules rather than organisms. More than 200 plant-viruses or virus-strains are known, and only about 20 have been subjected to serious chemical or physical study. These have been selected for detailed study largely because they give a highly infective sap, which retains its infectivity in spite of the various changes that go on in ageing leaf-extracts. These are more or less chemical criteria, and any uniformity which appears to run through the group of plant-viruses is at least as likely to be due to this initial selection as it is to be due to a genuine uniformity in the viruses. Animal-viruses have, from a chemical point of view, been chosen at random; that is to say they have been chosen for their social or economic importance. Those so far investigated, notably by Beard and his associates, have tended to be larger and more complex chemically than the plant-viruses, but it would be premature to make any generalizations until many more have been investigated.

The distinction between molecules and organisms, in any region where this distinction could be uncertain, is purely verbal. In so far as it can be defined, it is between materials that are handled by the methods characteristic of a biochemical laboratory and materials handled by methods characteristic of a biological laboratory. But many well-known materials are habitually handled in both ways. We all agree that *Bact. coli* is an organism, but when it is being disintegrated to make an enzyme-preparation or hydrolyzed as a prelude to amino-acid analysis, it is being treated as a substance and, but for the preliminary agreement, might be looked on as a molecule. The position with viruses is similar. No one has demonstrated that some of them are substances or macromolecules. Indeed, such a thing is not susceptible of demonstration; it is not a statement about the viruses but about the mental approach and technique of the research-worker. It has, however, been amply demonstrated that, as Beijerinck suspected, valuable information about their properties can be won by the methods of biochemistry.

Valuable as the contributions of biochemistry to the study of viruses have been, they are not without danger. The application of some chemical methods to the study of a group of substances does not guarantee the amenability of these substances to all other chemical criteria. Uniformity is the most important of these. In the study of the simpler molecules, on which the main structure of chemistry rests, any difference in composition between two molecules is quantitatively significant because the weight of an atom is an appreciable fraction of that of the molecule. Even the smaller proteins are so large that this is no longer true, and the replacement of one amino-acid residue by a different but similar one would not be detected by any of the elementary analyses or physical measurements so far made. *A fortiori* such a replacement would not be detectable in a virus. In the absence of any possibility of demonstrating that all the particles in a virus-preparation are identical, there seems to be little point in asserting that they are molecules. The only effect of this assertion is to rob a useful word of the meaning that it has in the more rigid discipline of chemistry. As soon as a particle has become so big that the introduction of, for example, a  $-\text{CH}_2-$  group has no longer an observable effect on the particle-size or analytical composition, the word molecule has become misleading (cf. Pirie, 1940; 1946). Clerk Maxwell (1875) distinguished clearly the use of the word by chemists, to mean identical primary particles of a substance, from the use by physicists, to mean a particle in a fluid that did not break up during the observation. This distinction is in danger of being disregarded, and the demonstration of physical molecularity is loosely taken to imply chemical molecularity as well.

The argument in the preceding paragraph is designed to show that, even if successive preparations of the same virus from different sources cannot be shown either to differ from one another or to be inhomogeneous, there is still no basis for the claim that all the particles are identical in the sense that those of, for example, sucrose are. Such an argument is not, strictly speaking, necessary, for even those viruses for which the molecular claim has been made most persistently are demonstrably variable and inhomogeneous. The particle-weight and analytical composition attributed by Stanley and his colleagues to tobacco mosaic have ranged over a wide field. Even in the same paper different values may be given; thus Gaw & Stanley (1947) quote phosphorus-values, one of which is 25% higher than the other, as evidence that a strain of tobacco-mosaic virus is the same when grown on tobacco as when grown on phlox. It is unlikely that such evidence would be acceptable in other fields of chemical research.

It is clear, both from first principles and from a consideration of the type of evidence that is actually published, that the idea of viruses as molecules in the strict chemical sense is misleading. Beard (1945; Hook *et al.* 1946) has ably presented the case against regarding some of the animal and bacterial viruses as molecules. He tends to contrast them, because of their variability in composition and particle-size, with the plant-viruses and other materials often classified as macromolecular. An experience of a fairly wide range of these substances, including plant-viruses, proteins, bacterial antigens, agar and hyaluronic acid, suggests that this distinction is unreal. The variability of these substances may not be so great as that of the

viruses which Beard has studied, but the difference is quantitative only.

#### 4. Nature of the Fundamental Virus-Particles

Variation between individual virus-particles or between successive preparations of the same virus can arise in many ways. There is no *a priori* reason why the property of being virus, that is to say of transmitting a certain set of symptoms or behaving in some other defined way, should be associated with a unique chemical structure. The virus-building mechanism may make a range of products, all active and similar, but not identical. It is equally probable that initially-identical particles should become non-uniform through association, dissociation, or the adsorption of components from the environment. Bawden & Pirie (1945) have some evidence that the last two processes operate to control the properties of tobacco-mosaic virus. In their view, the free virus aggregates in solution, but this aggregation can be prevented by other adsorbed materials. They suggest tentatively (1937a, 1945) that the primary particle is more or less spherical and smaller than the rods which are the predominant constituent of old or roughly-handled virus-preparations. Stanley stoutly defends the position that the rods, which Bawden and Pirie had described, are the fundamental particles, and that all others are derived from them. He has (Oster & Stanley, 1946; Sigurgeirsson & Stanley, 1947) published electron-micrograms purporting to show the original state of the virus in the cell. His technique, however, involves exposing the virus to that unphysiological fluid "leaf sap" which, as Bawden & Pirie (1945) have demonstrated, is a powerful aggregating agent. Furthermore, there are serious limitations to the use of electron-micrograms in getting evidence of this type (cf. Pirie, 1945; Crook & Sheffield, 1946). Stanley's position has the obvious merit of simplicity, but this simplicity can be achieved only by disregarding much of the available evidence.

#### 5. Combination of Virus with Tissue-Constituents

The presence of material, attached to the particles in a virus-preparation but not essential for the activity of the preparation, has been recognized with many other viruses. Curnen & Horsfall (1947, and earlier papers) have studied the complex that the pneumonia virus of mice makes with a constituent of lung and other tissues. Free virus can be made, and this will then combine with the tissue-constituent *in vitro*. It therefore seems probable that the complex is an artefact made during the extraction of lung by the original methods as a result of bringing together components not normally in contact in the tissue. Influenza-virus preparations contain material reacting with antisera against chick-embryo or mouse, depending on which host has been used for cultivating the virus (Knight, 1946). Virus free from these components has not yet been made, and it is therefore not possible to say whether, here also, the complex is an artefact, or whether some components of the host are essential for the stability of the virus-particle. Cohen (1946) has described a phenomenon in the T2 virus

of *Bact. coli* which may have a similar origin. When grown on a synthetic medium, the virus is associated with extra desoxyribose nucleic acid and this can be removed from it, without loss of virus-activity, by digestion with desoxy-ribonuclease. Here, therefore, an apparently homogeneous virus-preparation contains material inessential for virus-activity. There is no evidence showing whether it has any relationship with normal host-cell components or not. The tumour-viruses give many examples of similar phenomena. Carr, for example, has good evidence (1944) that the antibodies, built up in an animal carrying a Rous No. 1 sarcoma, progressively reduce the filterability of the tumour-virus, presumably by precipitating it in the interstices of the tissue. The only apparent difference between this and the other examples of complex-formation quoted is that the complex never appears in suspension. There is no evidence for anything analogous to antibody-formation in plants; it is therefore unlikely that precipitation of this type explains Bawden & Pirie's (1946) observation that the greater part of the virus in plants with tobacco-mosaic is not in solution but firmly attached to the structure of the leaf. If this phenomenon is at all general, it greatly widens the field of complex-formation.

#### 6. Conclusions

In recapitulation it may be said that our ideas about the nature of viruses are now based on much information, but that this has increased rather than diminished the complexity of the subject. It is a matter of observation that there is no clear demarcation between viruses and bacteria, and there is probably no demarcation between viruses and physiologically-active but synthesizable molecules. All the viruses purified so far have contained nucleoprotein, but this generalization may lack significance because the viruses that have been studied are a group selected to some extent on a chemical basis. Furthermore, the purified virus is the minimum unit capable of starting the infective process in a susceptible cell. It may well be that an essential preliminary to the process of multiplication is the accretion to the virus of various other cell-constituents. This view has for long seemed probable *a priori* (cf. Dale, 1935); the frequency with which viruses, if isolated by gentle procedures, are associated with host-cell constituents is confirmatory evidence for it. It becomes a matter of arbitrary definition at what point, in stripping away host-components from a virus, one is purifying it, and at what point one is modifying it. These considerations need emphasis because of the frequency with which the supposed facts of virus-research are used in discussions on other branches of biology. There are clearly resemblances between viruses and genes (Muller, 1922) or other tissue-components (Claude, 1941) but caution is necessary in arguing from these resemblances. In commenting on the position it would be difficult to improve on Beard's (1945) felicitous phrase: "Viruses are said to be living molecules and autocatalytic enzymes and are likened to genes and mitochondria—in short, a fabric of concepts has been woven of a plethora of wool with a paucity of warp."

This is a not inopportune time for a review of the present position of immunochemistry and of the contributions that chemistry has made to this branch of science. The phenomena of immunity are essentially chemical, and we might reasonably expect that some of its problems will soon be solved if a more sustained chemical and biochemical attack is made on them.

Ehrlich can be credited with some of the earliest efforts to apply the principles of chemistry to immunity. He believed that the combination of toxins with animal cells on the one

hand, and with antitoxins on the other, were processes which obey the ordinary laws of chemistry and physics. His "side-chain" theory, with its toxophore, haptophore and other receptor groupings, certainly became very complicated in the various modified forms which were developed to meet objections to his theory, but at least it gave stimulus to an immense amount of discussion and scientific investigation; above all, it gave a pictorial conception of the interaction of antigen and antibody by chemical reactions. These views were, however, strongly opposed by Bordet, who maintained that immune reactions take place as a result of physical or colloidal processes, with emphasis on adsorption. The comforting terminology of the early colloidal chemistry satisfied most immunologists for a long time, and, as Heidelberger (1946) aptly remarked, "many of those who once found it useful and comfortable still think of it with nostalgia". Evidence of this can readily be obtained from many textbooks of pathology and bacteriology, but it must be recorded with regret that in 1927 a well-known biochemist, surely in a moment of mental aberration, subscribed to the view that complement may merely be a name for a physical state of the serum.

During the past two or three decades the position has shown material improvement, in the eyes of the chemist, thanks to the efforts of such men as Arrhenius, Wells, Landsteiner, Zinsser, Heidelberger, Avery, Marrack and a host of others, who have tried to think of immunology in terms of chemistry. Above all, Landsteiner might perhaps be regarded as the father of modern immunochemistry. Wells' *Chemical aspects of immunity* (first published in 1924 and revised in 1929) was certainly a milestone recording progress in the development of this subject, and giving encouragement to those who had just joined the pilgrimage, but it was largely the laboratory investigations of Landsteiner over the period 1906-43 which formed the basis of our knowledge of immunological specificity. As befitting one who had served an apprenticeship in Emil Fischer's laboratory, Landsteiner was able to think of antibody formation and the reactions between antigen and antibody in terms of organic

chemistry; and the modern concept of the chemistry of serological specificity rests largely on his work and the work of those who followed his example. Avery and Heidelberger, with their isolation of the specific polysaccharides of the pneumococcus, and Heidelberger and his colleagues, with their use of analytical chemical methods for the study of antigen-antibody reactions, have done much to provide rational explanations for many immunological phenomena.

### 1. Mechanisms of Immunity

The chemist is particularly interested in the structure and composition of antigens and antibodies. A "true" or full antigen is a compound which on injection into an animal produces antibodies capable of reacting specifically with the antigen, e.g., by precipitating or agglutinating it. Certain polysaccharides and some other non-protein compounds, which, although incapable of inducing any marked antibody-formation when injected, can react *in vitro* with specific antibodies, are termed haptens (Landsteiner), and much information about the chemistry of immunity has come from the study of these compounds.

The view is widely held that antibodies may be the real key to immunity, but it also seems probable that some or all of them may act in collaboration with the phagocytes. Precipitation or agglutination of the bacteria or foreign substance may not actually occur *in vivo*, but there appears to be no doubt that chemical combination of antigen and antibody does take place in the animal body; the elimination of the precipitated or "neutralized" material requires the help of phagocytic cells, complement, and possibly other non-specific defence-agents of the body.

The study of phagocytosis has not been neglected by chemists (cf. review by Mudd, McCutcheon & Lucké, 1934), and the opsonins which facilitate and promote phagocytosis have also been investigated. There is, however, the need for a renewed attack on phagocytosis and opsonic action with the more modern weapons of chemistry.

In recent years, much interest has been shown in other non-specific resistance-factors of the tissues, such as leucotaxine (causing leucocyte emigration to the infected area), hyaluronic acid, hyaluronidases ("spreading" or "diffusing" factors), and lysozyme. Leucotaxine, described by Menkin (for the literature, see Hadfield & Garrod, 1942, and Boyd & Malkiel, 1947) has been isolated as a crystalline and extremely potent product having the properties of a polypeptide. Hyaluronic acid, present in certain bacterial capsules, is a polymer of acetyl-glucosamine and glucuronic acid, and the enzyme hyaluronidase has been obtained in a highly purified form and its polysaccharide-splitting activity fully studied. Lysozyme, which is widely distributed in nasal secretion, saliva, tears, leucocytes, and egg-white (Fleming, 1922) has been isolated as a crystalline protein (Abraham & Robinson, 1937; Alderton, Ward & Fevold, 1945); it has a molecular weight of about 17,000, and an iso-electric point between pH 10.5 and 11.

The immunological role of hyaluronic acid and hyaluronidases, and the significance of the production of hyaluronic acid by some bacteria, and of hyaluronidase by others, have yet to be elucidated. The functions of lysozyme are also not yet established, for most pathogenic organisms show little if any susceptibility to its action. The chemist has, however, paved the way to a full-scale attack by exposing

some of the mysteries of these tissue- and cell-defences; now that many of these resistance-factors are becoming available in a chemically pure state, there is a much greater hope for success in the study of these problems.

### 2. Antigens and their Immunological Specificity

Since most full antigens are proteins or protein-containing complexes, it is not surprising that the serological specificity of proteins has been extensively studied. As a result of this work (cf. reviews by Landsteiner, 1945; Boyd, 1943), we know that this specificity depends on the chemical structure of the antigens. It is not always possible by laboratory methods to detect chemical differences between two closely-related natural proteins which the rabbit can readily distinguish by producing antibodies which react with one protein and not with the other; but more refined chemical technique will almost certainly render this possible. Chemistry has undoubtedly made valuable contributions to our knowledge of antigen and antibody specificity, and much greater progress should be made in the future by closer collaboration between biochemists and immunologists.

Immunological activity is, of course, not confined to the proteins, for the specificity of certain bacterial and other cells is largely due to carbohydrates and carbohydrate-lipid complexes. Some purified lipids can also act as specific antigens. In all these cases a chemical attack has been made, and much useful information has been obtained about the chemical groups responsible for the serological specificity of these antigens.

### 3. Chemically-altered and Conjugated Protein-Antigens

An extensive study has been made of the specificity of protein-antigens by the attachment of various well-defined groups to proteins to produce complexes having serological properties different from those of the original protein. The most successful method, and one which has been used by numerous workers, is that introduced by Landsteiner & Lampl (1917); it involves the use of a compound containing a diazotizable amino-group and the coupling of the diazotized compound with a protein to form an azoprotein complex. Studies on a wide variety of azoproteins have shown that this conjugation gives the protein a new specificity dependent on the "determinant" group introduced, and on the spatial configuration in that group. A full account of these investigations is given by Boyd (1943), Marrack (1938) and Landsteiner (1945), and all that is possible here is a brief reference to a few fundamental discoveries. Landsteiner & van der Scheer (1932, 1934, 1939) attached peptides containing 2 to 5 amino-acid molecules to proteins, and found that although the specificity of these conjugated proteins was partly due to the nature, order, and the number of the amino-acid molecules attached, the predominant influence was exerted by the amino-acid at the free end of the peptide chain. Shortly before this, the same authors (1928) found that serological tests could readily differentiate between the *d* and *l* isomers of phenyl-(*p*-aminobenzoylamino) acetic acid and in a more striking way the isomers of tartaric acid (1929). In the latter case, the immunized rabbit differentiated sharply between azoproteins which differed only in the arrangement of the H and OH groups in the tartaric acid portion of the tartranilic acid linked to the protein. Fig. 1

indicates diagrammatically the delicacy of this serological differentiation.

FIG. 1. TARTARIC ACID AZOPROTEINS

Steric isomers of this type were also studied by Avery & Goebel (1929), who obtained serological differentiation between azoproteins containing glucose and those containing galactose. In further investigations on these carbohydrate-azoproteins, Goebel (1940) succeeded in immunizing mice against pneumococci of Types II, III and VIII by injecting into them antisera towards azoproteins containing cellobiuronic acid (a disaccharide containing one molecule of glucose and one of glucuronic acid). This production of an effective immunity towards an actual disease by the use of an artificial antigen containing a synthetic hapten marked a distinct advance in immunochemistry.

In more recent years Harington has introduced the use of the reaction between azides and the free amino-groups of proteins to produce conjugated proteins in which the haptenic group is linked to the protein by a peptide linkage. This elegant method (Clutton, Harington & Mead, 1937; Clutton, Harington & Yuill, 1938) has been successfully used for the production of antisera against thyroxine (for the references cf. Harington, 1944a) and aspirin (Butler, Harington & Yuill, 1940).

Protein specificity has also been studied by the direct introduction of atoms or small groups into the protein molecule, this process usually inducing in the protein a new specificity characteristic for the grouping introduced (cf. reviews by Landsteiner, 1945; Wells, 1929; Wormall, 1937). In this way, useful information has been obtained about immunological specificity, and indirectly about the structure of proteins. The actual determinant groupings in natural protein-antigens is not yet known, but the nature and order of the amino-acids in the polypeptide chains undoubtedly has a decided influence. The carbohydrates naturally linked to egg-white proteins do not appear to play any part in determining the serological specificity of these glycoproteins (Neuberger & Yuill, 1940).

#### 4. Bacterial and other Cell-Antigens

Important progress has been made in the investigation of the chemistry of the antigenic mosaic of the bacterial cell. In many instances the components of these antigenic complexes have been separated and identified, and their biological action investigated, and this field of immunological research has been "one of the most fruitful in discoveries of both theoretical and practical importance" (Dubos, 1945, p. 234).

The chemical nature of bacterial antigens has been well reviewed in this journal by Morgan<sup>1</sup> (1944a), with an account of typical haptens and antigens from some gram-positive and gram-negative organisms. Considerable progress followed the separation by Boivin and his colleagues in 1933 (for the literature, cf. Morgan, 1944a; Landsteiner, 1945), and by Raistrick & Topley (1934), of highly antigenic complexes containing specific polysaccharides and lipids.

The more-recent use of special reagents for the separation and partial degradation of the complexes has yielded non-antigenic undegraded specific polysaccharides and non-antigenic phospholipin-polysaccharide complexes. For example, Morgan & Partridge (1941, 1942; cf. also Morgan, 1943) have obtained evidence that the protein component of the phospholipin-polysaccharide-protein antigen isolated from *Bact. dysenteriae* (Shiga) and *Bact. typhosum* is a conjugated protein, and Freeman (1943) has obtained an antigenic complex from *S. typhimurium* which is believed to be a chemical entity; this complex contains specific polysaccharide (69%), a conjugated protein (16%), mixed lipids (3-4%), and an alcohol-soluble acetylated polysaccharide (about 8%).

To establish the exact constitution of an organic compound the chemist first analyzes it, and then splits it into its component pieces. A provisional formula might then be given to the compound, but final proof of this formula usually awaits synthesis of the compound from simpler substances of known constitution. As a natural corollary to the analysis of bacterial antigens, attempts have therefore been made, with considerable success, to re-combine the isolated polysaccharide and the conjugated protein, and thus to form complexes which are antigenic and which produce antibodies specific for the polysaccharide component. In a similar way, other non-antigenic polysaccharides, and the haptenic specific blood-group agglutinogens A and B, have been converted into full antigens by combination with a bacterial somatic conjugated protein (cf. Morgan 1943, 1944a).

Amongst other observations of special interest to chemists is that of Avery, MacLeod & McCarty (1944). These authors isolated from Type III pneumococcus a polymerized desoxyribonucleic acid which, when added to a medium in amounts as low as 1 part in  $6 \times 10^8$ , can effect the transformation of Type II pneumococcus into Type III, a change of specificity which is permanently retained by the organism.

#### 5. Blood-Group Substances

Much information has been obtained (cf. Morgan, 1944b<sup>2</sup>, 1947; Witebsky, 1946) about the chemical nature of the blood-group substances A, B and O, particularly the A substance, since it can readily be prepared on a large scale from hog gastric mucosa. The highly potent purified A substance contains 5.7-6.4% N, 9.2-11.5% acetyl and 27% hexosamine (Morgan & King, 1943). Purified preparations of these group-specific substances have been used to reduce the anti-A (or anti-B) titre of group O blood to be used for transfusion (Witebsky, Klendshoj & Swanson, 1941), and also for injection into man to produce strong grouping-serum (Witebsky, Klendshoj & McNeil, 1944).

## 6. Antibodies and the Antigen-Antibody Reaction

Antibodies have been shown to be adapted or slightly modified serum-globulins, and their combination with various antigens in the precipitin reaction has been studied quantitatively by many workers, notably by Heidelberger and his colleagues. From chemical analyses of antigen-antibody precipitates a quantitative theory of the precipitin reaction was developed (Heidelberger & Kendall, 1935, and later papers; cf. reviews by Heidelberger, 1939, 1946; Kendall, 1942). The data obtained support the view that both antigen and antibody are multivalent, thus giving strong quantitative support for the "lattice" or "framework" theory of Marrack. Space does not permit further discussion of these fundamental analytical investigations, and of the equations and formulae developed to give a quantitative expression to the precipitin and other immune reactions, but the reader is referred to the stimulating and provocative reviews by Boyd (1943), Pauling (1940) and Pauling, Campbell & Pressman (1943). Useful accounts of the applicability of quantitative methods in immunochemistry are given by Kabat (1943) and Treffers (1944), and the nature, properties and formation of antibodies have been reviewed by Marrack (1942) and Haurowitz (1947). Methods for the quantitative determination of antibodies are now fully established (cf. Heidelberger, 1946), and according to Dubos (1945, p. 272) this ranks as "one of the great achievements of immunochemistry".

## 7. Inhibition Tests (Competitive Inhibition)

Modern investigations in chemotherapy have been largely re-orientated since the recognition that many bactericidal compounds, narcotics, and other drugs act by competition. It is often overlooked, however, that competitive inhibition in enzyme systems had been studied at an earlier date, and that the specific inhibition of serological reactions had also been described. Landsteiner (1920) showed that simple substances having structures identical with, or similar to, the hapten group of azoproteins could specifically inhibit the reaction between the azoprotein and its antiserum. Since that date, serological inhibition-tests have been used very extensively (cf. reviews by Marrack, 1938; Boyd, 1943; Landsteiner, 1945) and valuable information has thereby been obtained about the "determinant" or serologically-dominant groups in many antigenic complexes and chemically-altered proteins, and about serological specificity in general. This inhibition-test technique greatly simplified many immunochemical studies and greatly widened the field of investigation. Work carried out in Landsteiner's laboratory showed, for example, that the specificity of iodinated-protein antigens is due to the 3:5-diiodotyrosine groupings (Wormal, 1930). Proof that the inhibiting compounds actually combine with the antibodies was obtained by Marrack & Smith (1932), and later by Haurowitz & Breinl (1933).

## 8. Hypersensitivity or Allergy to Simple Chemical Compounds

The acquired hypersensitivity of an individual to a protein or a protein-containing complex might be explained by assuming that previous exposure to the material had produced antibodies which rendered the subject specifically allergic or hypersensitive to the "allergen". Hypersensitivity to simple compounds ("drug allergy") could not be so readily

explained, until it was gradually realized that the exciting agents might have been rendered fully antigenic by combination with the body-proteins to produce new protein-complexes which were "foreign" and therefore antigenic to the body. Full confirmation of this view has been obtained by various workers, and Landsteiner & Jacobs (1935) were able to sensitize guinea-pigs with dinitrochlorobenzene, picryl chloride, and many other comparatively simple aromatic compounds, several of which are known to produce hypersensitivity in man. Various workers have obtained further evidence of this formation of antigenic conjugates (cf. Landsteiner & Chase, 1937a, 1937b, and the review by Landsteiner, 1945); and Harington (1944b) and his colleagues have succeeded in sensitizing guinea-pigs to tetryl, and have obtained evidence that the sensitization is due to the action of the tetryl on the skin-proteins.

All types of drug allergy cannot, of course, be accounted for on the basis of combination of the drug with body-proteins to form a "foreign" protein. There is, however, an increasing amount of evidence that the ordinary protein molecule contains a variety of very reactive groupings, and that it can combine with many compounds which chemically are regarded as very inert; the trypanocidal drug suramin (Bayer 205), for example, firmly combines with serum- and other proteins (Dewey & Wormal, 1946). Thus it seems possible that immunochemical studies, and others concerned with the interaction of drugs and proteins, may help to throw some light on drug allergy.

## 9. Complement

Not many years ago complement was regarded as one of the insoluble mysteries of immunity, and the specific lytic action of this reagent or system was often referred to as a special physical property of the serum (for the early literature see Osborn, 1937). At last the faith of many chemists is gradually being justified, for three of the four known components of complement have now been isolated in a highly purified form. Many authorities regard complement as a keystone in the immunity defence-systems of the body, and a clearer knowledge of this agent should undoubtedly greatly improve our chemical knowledge of immunology. Work in this field has been greatly stimulated by the use of the more-refined methods of physical chemistry by, amongst others, Ecker and Pillemer (cf. Ecker & Pillemer, 1942; Pillemer, 1943) and Heidelberger. Exact details have been given (Bier, Leyton, Mayer & Heidelberger, 1945) for the titration of the four individual components of complement, and from many laboratories useful information is forthcoming about the chemical properties of these components and their role in serological tests (cf. reviews by Marrack, 1942; Kabat, 1946). Perhaps we shall not have to wait long now before we learn the chemical mechanism underlying the specific destruction of the fourth component of complement by ammonia and ammonium salts, and the specific adsorption or inactivation of the third component by an insoluble yeast-carbohydrate. We might also find the answer to the question as to whether one of the components is an enzyme and another a lipid.

## 10. Miscellaneous

There are many other branches of immunochemistry where vigorous chemical attack has been, and is being made, with considerable success. It will merely be possible here to mention a few reviews and other publications, and perhaps the reviewer will be forgiven if this selection is considered rather arbitrary and haphazard. Reviews and discussions on anti-hormones (Thompson, 1941), anti-enzymes (Sevag, 1945), the production of antisera against thyroxine (Harington, 1944a), the chemistry of viruses (Andrews<sup>3</sup>, 1944; Pirie<sup>4</sup>, 1946), nutrition and resistance to infection (Schneider, 1946) and several papers on the production of antisera against the "sulpha" drugs, various antibiotics and carcinogenic compounds, indicate some of the problems which have interested immunochemists. Isotopic tracers are also being used to study immunity (Schoenheimer, Ratner, Rittenberg & Heidelberger, 1942; Heidelberger, Treffers, Schoenheimer, Ratner & Rittenberg, 1942; Bournsnel, Dewey, Francis & Wermall, 1947), and immunochemical methods have been used to study the action of mustard gas on proteins (Berenblum & Wermall, 1939; Bournsnel, Francis & Wermall, 1946). Pauling (1945) has given an excellent account of molecular structure and intermolecular forces in relation to immunity, and a modern claim has been made (Pauling & Campbell, 1942a, 1942b) that antibodies can be made artificially in the test-tube. Northrop (1942) has isolated a crystalline diphtheria-antitoxin.

## 11. Possible Future Developments

The reactions of an immunochemist who might happen by chance to glance at this review 30 or 50 years hence are difficult to anticipate. They are fairly certain to be somewhat critical, but nevertheless the temptation to speculate on possible future developments in immunochemistry is too

great to be resisted by the present reviewer. It seems probable that more of the "heavy guns" of chemistry and physics will be brought into action, and that more of the modern weapons, including radioactive and stable isotopes, will be brought into play. The USA, by virtue of its good fortune in having large supplies of these special isotopes available for tracer work, will almost certainly take a leading part in these investigations. Just as the isotopic-tracer method has solved some of the most complex problems of biochemistry, so it should help to explain some of the mysteries of immunity.

Further advances might also be expected by the use of antibodies against vitamins, enzymes, hormones, and drugs of special chemotherapeutic interest. Immunochemical methods might, for example, throw some light on the production of drug-resistant strains of micro-organisms, and if there is an undue development in nature of these drug-resistant strains, more reliance might have to be placed on immunological methods of treatment. Another possible development is the extended use (perhaps therapeutic) of nucleic-acid derivatives, similar to that isolated by Avery and his colleagues, for the transformation of organisms into less-virulent strains, and for producing mutations of micro-organisms for biological investigation.

More chemical information about the blood-group factors, including the Rh factors, should almost certainly be obtained before very long, and this might help considerably towards solving some of the remaining problems of haemagglutination in blood-transfusion and pregnancy.

There are many other avenues which are fairly certain to be explored, but sufficient has been said here to indicate a few of the contributions which chemistry has made, and will make, in the study of immunology. It might also be claimed that immunochemistry has a double role, for even as the chemist can assist in revealing some of the mysteries of immunology, so can immunological methods be profitably used to study some of the general problems of biochemistry.

The manifestations of life arise from a multitude of chemical reactions which are accelerated by a corresponding variety of protein molecules, the biological catalysts which we call enzymes. In this respect, life and catalysis are synonymous

\* Alan Johnston, Lawrence and Moseley Fellow.

terms. For most people, the great ingenuity of these reactions, and their importance in metabolic processes, excite much more interest than the nature of the molecules which catalyze them. This is not at all surprising, since the nature of an enzyme is wrapped in the greatest problem which confronts mankind—the elucidation of protein structure.

As far as we know, most enzymes, and therefore most proteins, are corpuscular, and an exact formulation of their structure demands a knowledge of the number of separate peptide chains in the molecule, the sequence of amino-acids along the chains (which are not themselves necessarily identical), the way the chains are folded, and the manner in which the folded individual chains are brought together to form the native protein molecule. It is recognized that certain patches on the molecule, consisting of a precise arrangement of chemical groups, are responsible for enzyme activity and for the specificity of the catalyzed reaction. In many enzymes, sulphhydryl groups participate in this spatial array of groups, but others are also involved. The existence of such groupings raises another fundamental problem of the structure of proteins: whether they arise by the manner of folding of the peptide chain, or from a formalized fold by the sequence of amino-acids along it. Such questions have a teleological flavour until the mechanism of protein synthesis is elucidated.

### 1. Types of Fibrous Protein

In the light of these immense problems, it has seemed more profitable to investigate those types of proteins which, superficially at least, are not quite so complex. These are

the fibrous proteins, in which the polypeptide chains are fully, or almost fully, extended, as in collagen (Astbury, 1940), silk, feather keratin (see Astbury & Bell, 1939); or show a regular and probably simple type of fold as in epidermal appendages (hair, horn), the epidermis itself (Rudall, 1946), fibrinogen (Bailey, Astbury & Rudall, 1943), myosin (Astbury & Dickinson, 1940) and tropomyosin (Bailey, 1946). Such proteins have lent themselves well to x-ray studies, since their diffraction patterns can be interpreted in broad outline, though much of the detail is unexplained. Of these proteins, the collagens and keratins serve either as supporting or protective structures, but others like fibrinogen, myosin (the contractile agent in muscle) and tropomyosin, whose properties suggest that it may be a small unit of myosin itself, are more truly functional. We shall consider these latter proteins in relation to their biological function, their structure and amino-acid composition, and attempt an interrelation of these several aspects. All three proteins are of mesodermal origin but, as we shall see, the evidence from structure alone does not suggest a fundamental difference from the proteins of ectodermal origin (hair, fibrils of the epidermis; Rudall, 1946). All possess the characteristic  $\alpha$ -pattern, indicative of a regular folding of the polypeptide chain, all are reversibly elastic and can be transformed to the  $\beta$ -form which is characteristic of certain naturally-occurring keratins. There does not appear to be any well-marked histogenic relationship between proteins; collagen, for example, is derived from mesenchymal mesoderm but is quite distinct constitutionally from the mesodermal proteins cited above.

## 2. Soluble Fibrous Proteins

Whilst the fibrous character of keratins, collagens, elastin and reticular tissue is obvious from their mechanical properties, the soluble fibrous proteins are not so easily isolated, and may be more numerous than is generally recognized. Biologists have been aware that anisometric particles may be present in the protoplasm of all cells (Lawrence, Needham & Shen, 1944). Their existence has been inferred largely by optical and other physical methods, but nothing is known of their nature. It has even been suggested that such molecules may arise by the unfolding of corpuscular proteins (Lawrence, Miall, Needham & Shen, 1944). This seems most unlikely, for there is no reason to suppose that anisometric proteins are any less organized than their formulated precursors; fibrinogen and myosin are both sensitive to their environment in respect of physical changes and impairment of biological properties. They must be built by a mechanism just as specific as those presumed to elaborate a corpuscular protein; an extensive unfolding process would tend to a randomness unsuited to Nature's ends. We must thus exercise some caution in interpreting the structure of the keratin, epidermis, myosin, fibrinogen (k-e-m-f) group as something rather simple. That they appear to have a common small-scale intramolecular pattern, which is built up into a grid-structure of side-chain to side-chain and back-bone to back-bone, helps us to a visual interpretation of structure which is lacking for the corpuscular proteins. But it is evident from the results of small-angle diffraction (see Astbury, 1943; Schmitt, Bear, Hall & Jakus, 1946) and electron-microscope studies (Hall, Jakus & Schmitt, 1945), that proteins both of  $\alpha$ - and  $\beta$ -type often possess a larger repeating-pattern superimposed

upon the smaller which so far has defied exact interpretation. It is as though we saw the small repeating units of a tapestry and not the integrated pattern.

## 3. Structure of the Keratin-Epidermis-Myosin-Fibrinogen Group

In what follows, we should be sure of what is fact or near-fact, and what is hypothesis, and to what extent our knowledge of fibrous proteins surpasses that of the main body of proteins which we call corpuscular. Firstly, we can differentiate by x-ray diffraction those families of proteins which both structurally and otherwise are quite distinct: on the one hand, the collagen group, and on the other, the k-e-m-f group. The distinction between the two is explained and supported by analysis, since the anomaly of the restricted length of the amino-acid residue in collagen could arise from the large numbers of proline, hydroxyproline and glycine residues occurring in the *cis* position in the peptide chain. The k-e-m-f proteins, however, consist predominantly of L-amino-acids with bulky side-chains which can be disposed only in the *trans* configuration.

Secondly, within the k-e-m-f group itself, x-ray evidence, supported by elasticity data, distinguishes between the extended proteins of  $\beta$ -type (e.g. feather keratin) and the regularly-folded proteins of  $\alpha$ -type. These latter are the more widely distributed, for the  $\beta$ -keratins are largely an evolutionary development in the epidermal structures of reptiles and birds. The  $\alpha$ -types can in all cases be transformed to  $\beta$ -types, sometimes by the simple process of stretching, sometimes by more-complex techniques, and this transformation is reversible. The artificial  $\beta$ -keratins do not possess the complex, rich, large-scale pattern found in feather keratin.

Thirdly, the interpretation of the gross structure of  $\alpha$ - and  $\beta$ -keratins has been built up from many-sided evidence. The simplest picture that we can conceive for  $\beta$ -keratin is one in which the extended polypeptide chain is juxtaposed with another in the direction of the side-chains to form a sheet or grid; these latter are then built up into a crystallite by piling one sheet on another, the sheets being held together by attractions between the peptide bonds of neighbouring back-bones. The three fundamental spacings of the  $\beta$ -keratin pattern, 3.33 Å. in the direction of the fibre axis, and 4.65 Å. and 9.7 Å. at right-angles to it, are indeed those we would expect for the average amino-acid residue-length, back-bone and side-chain spacing respectively; but further, Astbury, the pioneer in these studies, proved that these last two spacings were at right-angles to each other. There is in addition much chemical evidence, again supported by elastic properties, that the main chains in keratin proper are cross-linked with disulphide bonds arising from cystine residues present in rather large amounts. This again suggests that side-chains of neighbouring polypeptides lie in the same plane.

With regard to  $\alpha$ -keratin, the structure proposed is rather more tentative. Assuming that the structure of  $\beta$ -keratin is correct, the problem is to formulate a folding of the grid such that five observed experimental premisses are upheld: (i) the fold is 5.14 Å. long and must comprise three residues; (ii) the  $\beta$ -form must be approximately twice as long as the  $\alpha$ ; (iii) the densities of  $\alpha$ - and  $\beta$ -forms must be the same; (iv) the integrity of the grid must be preserved on stretching,

i.e. the side-chains must not swing round the main chains but must maintain their general directions; and (v) there must be sufficient room for the side-chains. It seems significant that a simple fold, maintaining (iv), i.e., the folding of the grid in a direction at right-angles to the side-chain direction, can be made to fulfil the other requirements, and to reveal another probable feature—the close-packing of side-chains, which are disposed as triads on either side of the main chain (Astbury, 1941, 1942). In this we see at once a factor which endows the  $\alpha$ -form with great stability, since individual groups of each triad might possess strong attractions for each other, as between acid and base, or between paraffinic side-chains. This model of Astbury's cannot be considered final, but as a working hypothesis there seems no reasonable alternative.

In any more-detailed interpretation of the structure of  $\alpha$ - and  $\beta$ -keratins, we are on much more uncertain ground, whether it be in the detailed composition of the fold, or in the higher level of molecular organization which concerns the larger repeating units lying at the limit of resolvability by x-rays but potentially resolvable by electron-optics. Yet it is clear that, by comparison, what knowledge we have of the fibrous proteins surpasses that for the corpuscular proteins, where only in very recent times has a modest beginning been made in the elucidation of their architectural complexity.

#### 4. Interrelation of the Soluble Fibrous Proteins

##### a. General Similarities

When the soluble members of the k-e-m-f group are compared, the similarities revealed by x-rays extend to physico-chemical, chemical, and biological properties (Bailey, 1944). Fibrinogen, myosin and tropomyosin all have globulin-like solubility, are salted-out at low ionic strengths, and have similar isoelectric points. When dried by mild methods, the  $\alpha$ -pattern is maintained, even where the process involves a loss of solubility or "denaturation". This is an important property and one distinguishing them from the corpuscular proteins, which usually pass to disoriented  $\beta$ -chains on denaturation. There is nothing to suggest that the transformation to the  $\beta$ -form plays any part in the biological role of these proteins. Purified fibrinogen, subjected to the action of thrombin, gives rise to an anastomosis of fibrin filaments which are also of  $\alpha$ -type (Bailey *et al.* 1943). In living muscle, the myosin filaments give rise to an  $\alpha$ -pattern which, surprisingly enough, is maintained during physiological contraction, where in fact we might expect a transformation indicative of a more folded form (Astbury, 1947). There are compelling reasons to suppose that if physiological contraction does involve an intramolecular folding of chains, this lack of disorientation is more apparent than real. X-rays pick out only the crystalline parts of the system, and during moderate contraction the less-crystalline parts will begin to fold first, so that disorientation is delayed. Such an effect is seen in the true keratins.

##### b. Significant Functional Similarities in Fibrinogen and Myosin

Whatever the detailed mechanism of clotting or of contraction, it seems likely from the nature of the processes that changes in the aggregation of the two proteins are concerned, and this is in keeping with the large numbers of polar groups

present. Recently, evidence has been obtained that the action of thrombin on fibrinogen is two-fold, involving the liberation of SH groups and subsequent re-forming of disulphide bridges between adjacent chains (Lyons, 1945). If this is so, it no doubt represents the trigger-mechanism for the aggregation of other side-chains. More important, perhaps, it suggests for fibrin the type of bonding which is accepted for wool and other keratins. These developments are made even more interesting by recent findings on the importance of SH groups in myosin, and their role in an interaction which gives rise structurally to something of the nature of a fibrin clot. To extend the analogy, we must digress to consider some of the properties of myosin.

After the isolation of myosin from the fibril, it soon became apparent from studies of flow-birefringence, elasticity, and x-ray diffraction, that the protein possessed all the fibrous properties which might be expected of the ultimate contractile mechanism, and the large amounts present in muscle supported the idea. The energy for contraction must clearly be derived from some reaction capable of building up the potential energy of the polypeptide chains. In point of time, it was known that the break-down of adenosine triphosphate (ATP), a substance containing two labile, energy-rich phosphate groups, was more or less coincidental with contraction, and the subsequent work of Liubimova & Engelhardt (1939) showed that purified myosin itself was capable of splitting ATP. Efforts to separate ATP-ase from myosin have failed, so that the linking of ATP as the direct energy-provider for the intramolecular contractility of the myosin filament seems probable, though the precise mechanism is obscure. The difficulty lies in the fact that the break-down of ATP to adenosine diphosphate and free phosphate cannot contribute to the potential energy of the protein chains, unless *in vivo* the phosphate is transferred to a protein side-chain or an end-group:

Side by side with the ability to split ATP, myosin *in vitro* interacts with another remarkable protein-component of the fibril, actin, first isolated by Straub (see Szent-Györgyi, 1945) and intensively studied by the Szeged school. Little is known of the nature of actin. The addition of actin to myosin results in a gelation due to the formation of "actomyosin", which in the electron-microscope is seen to be a highly anastomosed system of protein filaments, reminiscent of the structure of a fibrin clot (Perry & Reed, 1947). In very low concentration, ATP is capable of breaking up the system into its original components, and the viscosity falls. These phenomena cannot satisfactorily be fitted into a scheme of contraction except in a very speculative manner, and it seems wiser at the moment merely to record them. The interesting feature of the reaction, recently shown by Bailey & Perry (1947), is that the viscosity-increase occurs only if the SH groups of myosin are intact; if they are oxidized or substituted, the formation of actomyosin is prevented. Thus there appears to be a co-ordination of the actin with the SH groups of myosin, but on the actin side of the partnership, the groups responsible are unknown; they are not, however, SH or pyrophosphate groups. This SH property links a purely colloidal reaction of myosin with its ATP-ase activity, since this too depends upon the presence

of intact SH groups. Moreover, the extent of inhibition of actomyosin-formation runs parallel with the inhibition of ATP-ase activity as the SH groups are progressively substituted or oxidized (Bailey & Perry, 1947), and it would seem that the same groups are responsible both for enzyme activity and for the colloidal reaction. This receives independent support from the fact that ATP participates in both, and the mechanism of its action could be explained by a competition between actin and ATP for the active enzyme centres. By its ability to prevent actomyosin formation, the affinity of ATP for myosin must be very much greater than that of actin.

In the light of these facts, it is important to record that, in addition to other common properties of fibrinogen and myosin, SH groups play an important, even vital, role in their separate reactions. The importance of SS bonds in the structure of the true keratins needs no emphasis.

#### *c. Possible Relation of Myosin and Tropomyosin*

The recently discovered tropomyosin (Bailey, 1946) has been obtained in crystalline form from the skeletal muscle of the rabbit and whiting, and from pig cardiac muscle. It is thus of wide-spread occurrence, and all evidence suggests that it is a component of the fibril and not of the sarcoplasm. Though water-soluble after isolation, it is best obtained from ethanol-ether-dried mince by extraction with strong salt solution, indicating that in situ it forms a complex with some other protein and possibly with lipid. In salt solutions it exists as a homogeneous solute of molecular weight 90,000, but the removal of salt by dialysis results in an enormous increase of viscosity, due to the aggregation of molecules by electrostatic interaction into long fibres (300A. in width and 3000-6000A. long) which exhibit positive flow-birefringence. The ultimate molecule itself is highly asymmetric and composed of either one or two chains in the  $\alpha$ -configuration.

The mere fact that tropomyosin is the first protein of  $\alpha$ -type to be both crystalline and fibrous renders it of particular interest, quite apart from its possible function in muscle, which as yet is quite unknown. The properties of tropomyosin suggest that it may be a unit from which the myosin chains are in part elaborated. In all its physico-chemical properties, it is the prototype par excellence of myosin itself, and is built on the same intramolecular plan; its method of preparation suggests an intimate connexion with the structural proteins of the fibril. If the role we have suggested for tropomyosin is correct, it is difficult to answer why it exists free at all, except to note that nothing whatever is known of the mechanism of protein synthesis. There is the indirect evidence that in strong urea solutions myosin does in fact depolymerize to units of the size of tropomyosin, a process which affects only the secondary valence forces and not covalent bonds of the polypeptide chain. From a common-sense point of view, it seems almost impossible that a filament of the dimensions of the myosin particle can be rolled off fully-fashioned from its template, but more probable that, as in the transformation of fibrinogen to fibrin, it is built up from smaller units. We have also the example of the interaction of one tropomyosin molecule with another to give a fibrous product and of the further interaction of myosin and actin to give a highly aggregated complex. The supposition, then, that protein fibres are built initially by interaction of fairly large units signifies more than an intuitive belief.

If the analyses of myosin and tropomyosin were identical, the hypothesis would be unshakeable. In actual fact, they are very similar in certain respects: in the high lysine and arginine, and low histidine contents; in the amounts of tyrosine, leucine, valine, proline, methionine, serine, and the very high contents of glutamic acids and identical amounts of aspartic acid. Altogether, both molecules are the most polar (of mixed valency type) that have been encountered. There are differences, however, which leave no doubt that myosin is not built solely from tropomyosin units, even allowing for the fact that a "pure" myosin has not been analyzed. Differences are found in the relative amounts of certain amino-acids and in the absence of tryptophan and glycine from tropomyosin. This is a discouraging aspect in elucidating the relation of the two proteins and complicates, rather than denies, the hypothesis, for it represents but one example of a more general problem.

#### 5. Chemical Make-up of Interrelated Proteins

As we pass from keratin to myosin, it is difficult to see any similarity in chemical composition; in other words, the  $\alpha$ -fold can be maintained in spite of chemical differences. Astbury has attempted to explain this fact by assuming that whole groups of amino-acids are important rather than individual amino-acids. In particular, he has suggested that k-e-m-f proteins possess an alternation of polar and non-polar groups along the chain, which, by reference to the  $\alpha$ -model, gives rise to an alternation of triads, all polar on one side of the chain, and non-polar on the other (Astbury, 1941, 1942). Such an arrangement would endow the  $\alpha$ -form with the elastic properties which in fact it possesses. This formulation cannot strictly be upheld, since it implies that in the k-e-m-f proteins, the polar groups must comprise 50 % of the total; the figures for wool, fibrin, myosin and tropomyosin are 45 %, 54 %, > 57 % and 63 %, respectively.

Here, then, we reach something of an impasse in the finding that the  $\alpha$ -fold can exist in spite of, and sometimes by the similarity of, the amino-acid make-up, and other avenues need to be explored. As a general problem, arising from considerations of the stoichiometry of proteins, Astbury has discussed the possible ways of realizing residue interchange (Astbury, 1943). Either there may be a sequence of certain types of residues allotted to definite sites, thus giving rise to a stoichiometry of types and not of individual residues; or there may be a variable grouping of chains or even of grids of constant composition. The arguments presented in the case of myosin and tropomyosin would favour the latter idea, which also finds support from recent work on corpuscular proteins. There is both physical and chemical evidence that many proteins consist of more than one polypeptide chain. They may depolymerize in urea, in slightly acid or alkaline solutions, in very dilute aqueous solution, and contain  $\alpha$ -amino groups capable of chemical reaction and marking the terminal acid of each separate polypeptide chain. In the case of insulin, the sub-molecules of molecular weight 12000 contain 4 peptide chains, one pair of which differs from the remaining pair in end-groups and in amino-acid composition (Sanger, 1945). Is this then the key also to the chemical variations in the k-e-m-f group? If so, it implies that several types of sub-unit are characteristic of the  $\alpha$ -proteins, and these are brought together in varying proportion to serve particular ends; it implies too that

- References

The past few years have seen such intensive study of the plasma-proteins, and the information accumulated is so extensive, that a short review can indicate only a few salient features. The outburst of activity may be attributed predominantly to the refinement of the technique of electrophoresis, and to the combination of the precise data so gained with that from physiological, pathological and immunological investigations. By the early 1930's, a considerable bulk of data relating to the plasma-proteins was available, as a result of studies on "salt-out" and solubility, in conjunction with osmotic pressure and, latterly, ultracentrifugal studies.

Before proceeding to the discussion of more recent data, it may be of value to summarize broadly the position at that time.

Three types of protein were distinguished in plasma: fibrinogen, globulin and albumin. It is in this order that these proteins precipitate from plasma as the concentration of neutral salts, such as ammonium sulphate, sodium sulphate or sodium phosphate mixtures, is progressively increased, either by the addition to the plasma of saturated solutions of the salts, or by the direct solution of the solids in the plasma. Inflections in the curves relating the amount of protein precipitated to the concentration of added salt were utilized in attempts to establish the individuality of the components, and also in the development of methods of separating one from another. Two other main variables, pH and temperature, gave added flexibility to the preparative procedures. Similar techniques were used in the examination of the deviations from the normal distribution which were found to occur in pathological conditions, during the course of immunization procedures, and also for the isolation from plasma of protein fractions associated with specific biological activity.

Fibrinogen was sharply distinguished from the other plasma-proteins by its property of forming a fibrin clot as a result of the enzymic activity of thrombin. Albumin had been obtained in crystalline form from some species, and though relatively well defined, was already succumbing to subfractionation. The complexity of the globulin fraction had long been evident. It had been subfractionated into pseudoglobulin, a water-soluble portion, and euglobulin, a portion insoluble in the complete absence of salts, but soluble in dilute salt solutions. The order of molecular weight of these fractions was known, in some cases with a high degree of accuracy as a result of osmotic-pressure determinations.

This, briefly, was the general situation, though an enormous background of detailed information was also available.

### FIBROUS PROTEINS

*Continued from page 341*

Astbury's limiting or ideal in just this way, with keratin, tropomyosin at the other; it is not identical. It must be obvious that the attention must be group either biogenetically, biologically or chemically.

## 1. ULTRACENTRIFUGAL STUDIES

When a protein solution is subjected to an intense centrifugal field, the molecules sediment at a rate which depends on four factors: the mass of the molecule, the difference of density between the protein and solvent, the viscosity of the solvent, and the centrifugal field strength. The sedimentation velocity in unit field, corrected to standard solvent conditions, is designated the sedimentation constant, and is a characteristic of the molecule.

In the early 1930's, the effectiveness of the analytical ultracentrifuge was widely extended by the introduction of the Lamm-scale method for optical observations, by which the changes in refractive index associated with the boundary of a sedimenting protein could be accurately delineated (Svedberg & Pedersen, 1940). With this improvement it was possible, in addition to measurements of sedimentation constant, to obtain a measure of the homogeneity of the protein under examination. Further, in a mixture of proteins with differing sedimentation constants, an analysis of the quantities of the separate components present could be made, subject to certain reservations.

Using this method it was shown that the proteins of plasma were distributed into two chief groups of differing sedimentation constant. A comparison of the data from whole plasma with that obtained on derived salt-fractionated preparations showed that the sedimenting components corresponded with globulin and albumin, with respective sedimentation constants of about 7.0 and  $4.5 \times 10^{-13}$ .

By combination with the respective values for the diffusion constants, determined by the method developed by Lamm, the following molecular weights were derived, for globulin c. 170,000 and for albumin 70,000.

Though the sedimentation and diffusion constants are a function of molecular weight, their precise values are also dependent on the shape of the molecule. Recent measurements indicate that, although the molecular weight of fibrinogen is in the region of 600,000, owing to the elongated form of the molecule its sedimentation constant is so close to the more nearly spherical globulin molecule, that resolution does not occur in the ultracentrifuge. On this account the separate existence of fibrinogen in plasma is not demonstrable by ultracentrifugal studies.

In the plasma of some species small amounts of proteins of very high molecular weight occur, notably in the horse and pig; these appear as separate components in ultracentrifugal analyses and behave as globulins in their solubility relations.

## 2. ELECTROPHORESIS

In 1937 the initial data obtained with the improved electrophoresis apparatus devised by Tiselius were published (Tiselius, 1937). In addition to providing qualitative information about the number of components present in complex protein solutions, and precise values of their respective mobilities, the apparatus was adapted to the isolation of electrophoretically-homogeneous proteins in small quantities from mixtures.

The original simple "Schlieren" optical system used with the apparatus, though capable of indicating the presence of several components, gave no measure of the quantities in which they occurred. The Lamm-scale method was used to a limited extent, but owing to its laborious nature it was

quickly superseded by other methods, notably the "Schlieren scanning" and "diagonal Schlieren" systems, each of which provides quantitative data (Abramson, Moyer & Gorin, 1942).

The migration of a dissolved protein in an electric field is primarily determined by the net charge of the molecule, and since this is predominantly derived from the ionization of basic and acidic groups, it is in its turn a function of the pH and salt-content of the medium in which the protein is dissolved. Electrophoretic phenomena are therefore more closely related to the chemical structure of the molecule than sedimentation, which depends chiefly on size and shape.

From a mixture of proteins an electrophoresis-pattern is obtained in which each component gives rise, as in the ultracentrifuge, to a separate peak, closely allied to a normal distribution curve. This is subject to the migration having continued for a sufficient period under suitable conditions.

### a. Normal Plasmas

In his original examination of horse serum at pH 8, Tiselius (1937) distinguished four components. That with the highest mobility was identified as albumin, the remaining three as globulin, and designated  $\alpha$ ,  $\beta$  and  $\gamma$  in descending order of mobility. The more recent examination of human plasma indicates that six components are present: albumin,  $\alpha$ -globulin which, under special conditions, splits into  $\alpha_1$  and  $\alpha_2$ ,  $\beta$ -globulin, fibrinogen and  $\gamma$ -globulin in order of mobility (Longworth, 1942).

The quantitative constitution of normal human plasma determined by electrophoretic analysis, in which each component is given as a percentage of the total protein, is as follows (Edsall, 1947):—albumin 55; globulin  $\alpha$  14;  $\beta$  13.5;  $\gamma$  11; fibrinogen 6.5. These proportions remain remarkably constant in the normal individual, as the agreement between determinations in laboratories in many countries has shown.

The plasma of other species shows qualitative and quantitative electrophoretic deviations from normal human plasma with respect to the number, amount and mobility of the components. For example, in the horse the  $\beta$ -globulin is represented by two components  $\beta_1$  and  $\beta_2$ , and in the dog the pattern appears to be even more complex.

It may be of interest to point out the relation of the pseudo- and euglobulin fractions to the electrophoretic components. Both of these are mixtures; in pseudo-globulin the  $\alpha$ - and  $\beta$ -globulins predominate, whilst in euglobulin the chief constituents are  $\beta$ - and  $\gamma$ -globulins.

In human plasma, most of the protein-bound lipid is associated with the  $\alpha$ - and  $\beta$ -globulins. The albumin does not appear to have any carbohydrate attached to it, and in this respect differs from horse-serum albumin.

Although the plasma-components revealed by electrophoresis display a reasonable degree of electrochemical homogeneity, it is important to appreciate that this does not imply absolute chemical or physiological homogeneity. The wide range of physiologically- and immunologically-active proteins detectable in plasma is apposite to this point, and also the fact that the electrophoretically-homogeneous components are susceptible to further fractionation by solubility-methods. Further, the activity of proteins associated with specific biological effects is frequently so high in relation to mass, that the quantities present in plasma may

be far below the power of resolution of the electrophoresis-apparatus.

### b. Pathological Plasmas

The plasma and serum from a large number of pathological conditions have been subjected to electrophoretic analysis and already a considerable literature exists. To discuss the findings related to specific diseases would require detail beyond the scope of this article. In general, the quantitative distribution of the components has frequently been found to diverge, sometimes very markedly, from the normal. It appears to be exceptional for an entirely new component to appear in such plasmas.

In febrile conditions the proportion of  $\alpha$ -globulin is usually enhanced, whereas in nephrosis the albumin content is very low and the  $\beta$ -globulin is increased to a remarkable extent. Several conditions are associated with increases in the  $\gamma$ -globulin, notably cirrhosis of the liver and multiple myelomatosis, though in the latter abnormally high  $\beta$ -globulin contents may be found (Abramson *et al.* 1942). In infectious conditions there is also a tendency for the  $\gamma$ -globulin to be increased which is consistent with the finding that many antibodies are associated with this component.

This brief summary discloses that the changes occurring in the plasma-protein distribution in pathological conditions are not specifically related to any one disease. It is possible that the correlation of the clinical course of various diseases with alterations in the electrophoretic patterns may prove valuable in the assessment of therapeutic measures.

### c. Antisera

In the production of therapeutic antisera, the horse is most generally utilized. In this animal the antibacterial antibodies appear to be associated with  $\gamma$ -globulin which in hyperimmune serum is often very much increased in amount. In antitoxic sera the occurrence of two antibodies has been demonstrated, one associated with the  $\beta$ - the other with  $\gamma$ -globulin, and also differing from one another in certain biological characteristics. In the rabbit, antibodies appear usually in the  $\gamma$ -globulin (Abramson *et al.* 1942).

## 3. BULK FRACTIONATION OF HUMAN PLASMA-PROTEINS WITH SOLVENTS

Although, as already mentioned, it is possible to isolate the individual proteins from human plasma by electrophoresis, the scale on which this can be accomplished is very limited, and from this point of view the method is useful only on a research basis. In conjunction with bulk-fractionation methods, the apparatus has proved of inestimable value in providing an independent means of controlling and assessing improvements in the resolution of fractionation-procedures.

The separation of proteins has generally been carried out in very concentrated salt solutions, in the region of 2–3 molar, a procedure which has two main disadvantages. Firstly, high salt-concentrations mask specific salt-protein effects which may be utilized in improving the resolution of separations. Secondly, the products must be freed from the

precipitating salt by dialysis, a procedure difficult to carry out under the aseptic conditions desirable if the product is required for clinical purposes.

In attempting to separate proteins in a relatively pure condition from a mixture in aqueous solution, there are several variables which can be used to establish conditions such that a desired protein can be caused to precipitate more or less completely, leaving others in solution. The following are the determinant variables: pH, salt concentration, temperature, total protein concentration—and, as a result of recent studies, solvent concentration.

If a solvent is used to reduce the solubility of a protein, the electrolyte-content of the system can be maintained in as low a concentration-range as may be necessary. It is simpler to maintain aseptic precautions when adding solvents: indeed those solvents suitable for precipitation purposes tend to be bacteriostatic. Finally, the solvents can be removed from the products by freeze-drying, an operation easily performed under sterile conditions. The one disadvantage of solvents lies in their tendency to cause denaturation and loss of biological activity in proteins at room-temperature, and their use necessitates processing at temperatures ranging from 0° to –10° C. The precise examination of such methods has largely been due to E. J. Cohn and his associates, though sporadic papers have appeared in the literature as far back as 1908 (Cohn *et al.* 1946).

Such investigations were stimulated by the urgent needs of war and were initially directed towards the production of a stable liquid transfusion-material. This presents certain advantages over freeze-dried plasma, although under proper conditions the latter retains its properties for an indefinite period. Normal human citrate-plasma on storage tends to clot, and even if the fibrinogen is removed, precipitates form which simulate bacterial infection. These precipitates derive from the breakdown of complexes formed by lipoids with the plasma-globulins. In the production of a stable liquid transfusion-material from human plasma, two methods of attack are possible. The fibrinogen and globulins may be removed entirely, providing a stable solution of albumin. Alternatively, the fibrinogen and unstable lipoids may be removed from the plasma and the whole of the remaining proteins made available. The former method was followed in the USA, and in Britain the latter was explored.

The system of fractionation of human plasma with ethanol at low temperature developed by E. J. Cohn and his colleagues (Cohn *et al.* 1946) was primarily aimed at the preparation of pure human serum-albumin for transfusion. As the work progressed, a secondary objective developed: to separate the plasma-proteins into a limited number of main fractions corresponding as closely as possible to the individual electrophoretic components. These main fractions then provided the basis of various subfractionations, oriented with reference to specific biological activities. The following purified materials were made available in quantities and at concentrations adequate for clinical purposes: albumin, fibrinogen, thrombin,  $\gamma$ -globulin and erythrocyte isoagglutinins.

By the use of ether in the fractionation of human plasma, fibrinogen, thrombin, globulin concentrates and a stable delipoided transfusion-fluid have been made available in Great Britain (Kekwick, Record & Mackay, 1946).

#### 4. CLINICAL APPLICATION OF PLASMA-FRACTIONATION PRODUCTS

Perhaps the most versatile of the products of plasma fractionation are fibrinogen and thrombin (Bailey & Ingraham, 1944). Since the clotting-time of fibrinogen-thrombin solutions can be accurately controlled, a liquid mixture, which subsequently clots, can be applied locally. The tensile strength of fibrin clots, though also a function of other variables, increases with fibrinogen concentration, and solutions of fibrinogen up to ten times (2%) the corresponding concentration in plasma are readily attainable. The clots formed from such solutions have been used to suture severed nerves by a process of "soldering". Rather lower concentrations of fibrinogen provide, with thrombin, an excellent adhesive for the application and fixing of skin grafts, dispensing with the necessity for pressure dressings. Grafts fixed in this manner vascularize with extraordinary rapidity, and the tendency to bronze pigmentation appears to be reduced.

Fibrin films, resembling sheet cellophan in appearance, have been successfully used as dural substitute with marked absence of adhesion. The film is eventually replaced by fresh dural growth.

Somewhat less purified fibrinogen solutions are utilized in the production of fibrin foam. By suitable devices, these solutions are beaten to a finely dispersed foam which is "set" by adding thrombin and then dried from the frozen state. Such foams if rewetted tend to shrink rapidly, but

this can be prevented by baking the dried foam at 130° to 170° C. The dried foam will absorb almost its own volume of thrombin solution, and is used in conjunction with this for local haemostasis in internal surgery. The foam is allowed to remain in situ following operative procedures, and eventually becomes organized into the tissue without scar-formation.

It has been established that the antibodies in many infectious diseases are associated with the  $\gamma$ -globulin of normal adult plasma (Enders, 1944; Stokes, Maris & Gellis, 1944; Ordmann, Jennings & Janeway, 1944). Concentrates of this protein containing 15 g. protein/100 ml. have been very successfully used in the control of measles, and may be useful in infectious hepatitis. For measles, intramuscular injections up to 5 ml. are required. The use of similar concentrates prepared from convalescent-plasma pools from other infectious diseases, for example, mumps, has been examined.

The A and B isohaemagglutinins, which appear to be associated with  $\beta$ -globulin, have been purified and concentrated from pools of plasma of suitable blood-group. High-titre sera are required for accurate blood-group testing, and concentration methods make available the agglutinins from plasmas whose titre initially is too low.

Purified albumin solutions containing 25 g./100 ml. have been satisfactory for transfusion in cases of shock and hypoproteinaemic oedema.

Further research may indicate the clinical usefulness of other fractions derived from human plasma.

## AMINO-ACIDS IN NUTRITION

A. NEUBERGER M.D. Ph.D.

*National Institute for Medical Research, London*

- 1 Endogenous and exogenous metabolism of protein
  - 2 Protein storage
  - 3 Regulation of protein metabolism
  - 4 Clinical symptoms of specific amino-acid deficiencies
- References

Protein metabolism in general has been fully discussed in this journal in 1944 by Cuthbertson<sup>1</sup>, and the effect of protein on convalescence, recovery from injuries and burns has been considered by Peters<sup>2</sup> (1945) and Cuthbertson<sup>3</sup> (1945) respectively. It is not the purpose of this essay to bring these reviews up to date, but rather to consider some general problems of protein metabolism, to indicate gaps in our knowledge and to discuss possible future lines of work.

### 1. Endogenous and Exogenous Metabolism of Protein

Those early workers, such as Liebig, Boussingault, Voit and Pettenkofer, who introduced exact methods into the field of protein metabolism, were greatly impressed by the fact that the adult mammalian organism tends to keep its protein-content constant under the most diverse dietary conditions. Thus, a large increase of protein-intake leads after a very short lag to a corresponding rise in urinary N excretion, whilst starvation or a specific protein-deficiency produces a very marked reduction in N output. We know now that a similar regulation occurs in the metabolism of water and electrolytes. Voit (1866) suggested as an explanation that the protein molecules which form part of the living structure were metabolically almost inert, whilst the "storage protein" which was derived from the nitrogen present in the diet and which was assumed to circulate freely in the tissue-fluids was readily catabolized. This theory was further elaborated in a later publication (Voit, 1881) and has dominated reasoning in this field up to the last decade. Voit did not make it clear whether the differences which were supposed to exist between "tissue protein" and "circulating protein" were of a chemical or physical nature. He admitted that there may be an interchange between these two classes of protein, but emphasized that such reactions must be very slow. Rubner, who contributed a large amount of experimental work and a possibly disproportionate volume of speculative writing to the development of this field, investigated N excretion in subjects supplied with their full caloric requirements but lacking protein completely. The constant and small N

output observed under these conditions was ascribed to the slow rate of metabolism of the "living" or "tissue-protein". This "wear and tear" quota was assumed to be independent of dietary changes (Rubner, 1908; 1911).

The next important step in the development of this theory was taken by Folin (1905). This author compared changes in the composition of urine with the level of protein in the diet, and found that, whilst the concentration of some constituents such as urea was proportional to N intake, the excretion of other substances like creatinine was not influenced by variations in the diet. Folin suggested that the concentration of substances of the second group is a measure of the "endogenous" metabolism of the "tissue proteins" of Voit and is related to the "wear and tear" quota of Rubner. Excretion of urea and sulphate on the other hand corresponds mainly, but not exclusively, to the breakdown of excess dietary protein, and is related to "exogenous" metabolism. Thus Folin's extension of Voit's fundamental concept consisted mainly in relating the two branches of protein metabolism to certain nitrogenous substances in urine. However, Folin differed from Voit in one important point—he believed that the dietary protein is hydrolyzed to amino-acids and that these compounds of low molecular weight are mainly directly oxidized, without being first incorporated into "circulating protein".

Although the Voit-Folin theory was almost universally accepted, there have been a few dissentient voices. Thus Pflüger (1893) maintained that protein after absorption becomes quickly incorporated into the cell-structure and partakes in the general metabolic reactions of the organism. Much later Borsook & Keighley (1935) stated their belief that the sharp distinction between endogenous and exogenous metabolism was unjustified. However, the experimental evidence produced was not convincing, and it was only when isotopes were introduced into protein biochemistry by Schoenheimer, that the classical concepts had to be revised (for reviews see Schoenheimer & Rittenberg, 1940; Schoenheimer, 1946). Schoenheimer, Rittenberg and their colleagues used N<sup>15</sup> to mark the amino-acids or ammonium salts introduced in the diet, and followed the fate of the nitrogen atom in the organism. It was found that only a fraction of the labelled element was excreted in the urine; most of the nitrogen was found in the tissues. In fact, it may be inferred that all cells, even those of connective tissue and muscle, which had been thought to be particularly inert, are in a state of dynamic equilibrium with the nitrogenous compounds supplied in the diet.

Thus the old idea of Voit that the "tissue protein" is inert, and the modified theories of Rubner and Folin which assume that the protein turn-over of the body-substance is represented by the N excretion on a protein-free diet, are equally incorrect. Instead, we have to assume that the catabolic and anabolic reactions take place at a great speed and are fairly well balanced. Urinary N represents, therefore, only a small difference between the amounts of protein broken down and synthesized every day. However, the experimental facts on which the old theories were based need to be reconsidered, and it can be shown that the terms "endogenous" and "exogenous" metabolism can still be usefully employed, provided that their definition is adjusted to modern requirements.

In the old concept of Voit and Folin it was assumed that the terms endogenous and exogenous represented physical

<sup>1</sup> [BMB 486]    <sup>2</sup> [BMB 688]    <sup>3</sup> [BMB 691]

realities, i.e., the expressions were used to describe the actual fate of a metabolite in the body. Such an interpretation is now untenable, but the terms can still be used to describe items on a balance-sheet. Endogenous nitrogen has an exact physical meaning, if applied, for example, to the excretion of nitrogen on a protein-free diet, but if used in calculations of nutritional efficiency with protein-containing diets it represents, in general, nothing but a convenient fiction of nutritional accountancy. In certain cases a more precise meaning can be attached to the old terms. The excretion of creatinine in the urine is remarkably constant for any one individual in the absence of disease and is not markedly influenced by changes in the diet. The urinary creatinine is formed from the creatine-phosphate which is present mainly in muscle. Creatine in its turn is produced from arginine, glycine and methyl-donors, which all occur in the diet. Thus, the ultimate source of the carbon and nitrogen of creatinine, like that of urea and amino-acids, is largely exogenous. The difference between the two classes of compounds lies not so much in the nature of the different reactions involved, but in their rates. Creatine is formed in the body and creatinine is excreted in the urine at rates little influenced by the supply of precursors. Moreover, all the various reactions appear to be irreversible. The urinary creatinine may thus be endogenous in the sense that the amount formed is proportional to the mass of muscular tissue and is not related to the N content of the diet.

A somewhat similar position may exist with proteins. Schoenheimer & Rittenberg (1940) have shown that different organs vary greatly with respect to rate of N exchange. Further work is likely to show that different proteins, even in the same organ, are not metabolically active to the same extent. Thus, there will be some species of proteins which have a very high turn-over rate and correspond to the "circulating" protein of Voit. The same proteins may also increase in amount, if the intake of nitrogen is raised. Other types of protein molecules may be relatively inert and not quickly responsive to changes of diet. Such substances would represent the "tissue-protein" of Voit. Thus, these old terms may be used to describe not so much sharp qualitative differences between proteins, but quantitative variations in the rates of N exchange which are susceptible to unknown regulating factors. How far such differences are reflected in the chemical structures of the different proteins, only further research can show.

The use of labelled elements has not yet solved, but only shifted, the classical problems of protein metabolism. Are the rates of catabolic and anabolic reactions influenced by starvation, the N level in the diet, hormones, or specifically by some amino-acids? And above all, by what mechanism is the protein content of the body kept constant within fairly narrow limits in spite of the large changes taking place in the tissues? These are problems which can be tackled only with the aid of labelled elements.

## 2. Protein Storage

The assumption which has been made in the preceding section, that the N content of the adult organism tends to remain constant, is not wholly correct. It has been shown for man that superimposition of extra protein on a diet adequate for maintenance of body-weight and N equilib-

rium leads to marked retention of N (Cuthbertson, McCutcheon & Munro, 1937), and a similar result was produced by feeding carbohydrate (Cuthbertson & Munro, 1937). The storage of protein in the adult animal has recently been reviewed by Kosterlitz & Campbell (1945) who have themselves made important original contributions to our knowledge in this field. They have found that a fraction of liver-cytoplasm comprising protein, ribonucleic acid and phospholipin is quickly lost on reduction of protein below a certain level, or somewhat less readily by caloric restriction. This labile liver-cytoplasm is quickly regained if the protein intake is again raised above minimum requirements. Similar changes in other organs may occur, but they have been less carefully investigated. Another approach to the problem of protein storage has been made by Munro & Chalmers (1945). The work of Cuthbertson had shown that after injury, both in man and laboratory animals, there is an increase in the excretion of nitrogenous substances in the urine. This excessive excretion is reduced if the protein content of the diet is decreased, and becomes very small and transient on a protein-free diet. It thus appears that the well-fed organism has certain labile protein-reserves which are readily lost on injury. The amount of N lost is too large to be entirely accounted for by the labile liver-cytoplasm. The location of this reserve is unknown and it is also uncertain whether both this fraction and the labile liver-fraction differ chemically from the ordinary protein components of cell-cytoplasm. It is quite likely that they are again only items on a balance-sheet, and that their accumulation and mobilization are regulated by some unknown mechanism which is very sensitive to changes in the dietary intake of calories and protein.

The amounts of amino-acids and peptides present as such in tissues are small and are, quantitatively at least, unimportant as far as N storage is concerned. However, relatively large amounts of the tripeptide, glutathione, are present in all organs, but especially in the liver. The concentration of this peptide in the liver can be influenced within very wide limits by the composition of the diet (Leaf & Neuberger, 1947), and especially by its content of cystine and methionine.

## 3. Regulation of Protein Metabolism

The dynamic state of the body-constituents, as revealed by the isotope method, implies that oxidative, reductive and other reactions associated with large changes of free energy occur at a rate much greater than is indicated by the over-all energy-requirements of the organism or by the actual amounts of end-products excreted in the expiratory air and in the urine. It follows that reactions leading to a loss of free energy are coupled with those in which a net gain of free energy is produced. The question therefore arises as to how the relative constancy of basal metabolism, basal N excretion and N balance of the adult organism is ensured. It is at present impossible to answer these questions satisfactorily. It can be assumed that factors such as oxygen-tension, cellular concentrations of the various enzymes and coenzymes, and also those of the free amino-acids, influence the rates of the different catabolic and anabolic reactions which constitute protein metabolism. But there is evidence that, apart from these local cellular factors, hormones

may affect directly or indirectly the rate of reactions in which amino-acids take part.

It has been known for a long time that administration of thyroid increases N excretion. This effect may possibly not be specific but may result from the general stimulation of tissue oxidation. It is known that the "endogenous" N excretion is proportional to the basal metabolism, which is raised in hyperthyroidism. Recent American work has shown that androgens, especially testosterone, produce N retention in castrates, and similar results have been claimed for oestrogens. Moreover, both catabolic and anabolic effects on protein metabolism have been produced by the various steroids found in the adrenal cortex. Nothing is known about the way in which these substances act. One possibility is that at least some of these steroids, i.e., those lacking a hydroxyl group in position 11, act not directly on protein metabolism but indirectly through their effect on the excretion of sodium and potassium. Recent work of Hastings and others (see e.g. Hastings & Buchanan, 1942) has shown that various enzyme-reactions are greatly influenced by the ionic composition of the medium. It is thus quite likely that the rate of protein synthesis is affected by the concentration of sodium and potassium, respectively, and any hormone which regulates the excretion of these cations by the kidney may have an indirect influence on protein metabolism. The other group of biologically-active steroids of the adrenal cortex may affect protein metabolism through their action on carbohydrate oxidation.

More is known about the relationship between the pituitary and N excretion. It has been known for some time that the growth-hormone stimulates N retention. Part of this effect is undoubtedly due to the increased appetite which results from the administration of this hormone. But it has been shown in paired-feeding experiments, in which the controls received a diet of caloric value equal to that given to the animals injected with pituitary extracts, that increased growth occurs even under conditions of caloric restriction (Lee & Schaffer, 1934). Recent work by Young (1945) has fully confirmed these results; it was demonstrated that administration of pituitary extract to various animals, kept on diets which under normal conditions were just sufficient to maintain body-weight, produced N retention and, in the cat and dog, diabetes. The caloric requirements of these animals were largely covered by the combustion of fat, and this enabled the animal to retain N in spite of caloric restriction. Young suggests that this action on N balance is associated with the diabetogenic activity of these extracts. This may mean that the pituitary influences growth largely through its effect on carbohydrate oxidation. Some information is available which suggests that insulin enhances N retention, but further work on this point is required before the mechanism can be considered fully established.

The protein-sparing action of carbohydrate has been known for some time, and it has been generally assumed that this resulted from a purely energetic replacement of protein by carbohydrate. In other words the combustion of carbohydrate released a calorically-equivalent amount of protein for purposes of growth and tissue-regeneration.

But there is an alternative explanation. Various reversible and irreversible reactions in which amino-acids are concerned produce  $\alpha$ -keto-acids, many of which are associated with the metabolism of carbohydrates. Indeed, the keto-acids which correspond to those amino-acids which, according to isotope experiments, show the fastest turnover-rate—such as aspartic and glutamic acid—are most closely linked with the oxidation of glucose. It is thus possible that the protein-sparing action of carbohydrate may be due to the fact that glucose provides precursors of non-essential amino-acids, and that ammonia is then utilized for amino-acid synthesis instead of being converted into urea. In the absence of insulin, oxidation of glucose is inhibited, and the ammonia liberated in intermediary reactions is lost for purposes of protein formation.

#### 4. Clinical Symptoms of Specific Amino-acid Deficiencies

The essential amino-acids, i.e., those nitrogenous compounds which the mammalian organism cannot synthesize from substances normally present in the diet, have often been compared to vitamins. There are, however, important biological differences between these two groups of essential metabolites. Although complex interrelationships exist between certain vitamins, in general the requirements for various vitamins are largely independent of each other and additive. Moreover, many vitamins can be stored as such in the body. On the other hand, the formation of protein can proceed only if all the essential amino-acids are provided in the diet; single amino-acids can be stored only in insignificant quantities. It is therefore not surprising that, apart from exceptions to be discussed below, deficiencies of single amino-acids produce a clinical picture which is not specific for any one compound. What is generally observed is cessation of growth, loss of weight, hypoproteinaemia and a relatively mild anaemia. The animals get adapted, to some extent, to the lack of protein by reduction of N output to a minimum and by losing protein first from the non-essential organs. Such animals appear to be less resistant to infection, possibly due to interference with antibody production.

The position of the sulphur-containing amino-acids, methionine and cystine, appears to differ from that of other essential amino-acids. Methionine is, apart from being building-material of proteins, a donor of methyl-groups for the synthesis of choline and other substances. Cystine is a precursor of glutathione, of taurine and possibly other compounds of low molecular weight. It is therefore not surprising that a deficiency of these amino-acids produces more-specific clinical symptoms. With young rats, feeding of amino-acid mixtures lacking these sulphur-containing compounds produced an acute hepatic necrosis which could be prevented by the addition of either cystine or methionine (Glynn, Himsworth & Neuberger, 1945). However, later work has indicated that it is necessary for the production of necrosis to remove from the diet, not only these two amino-acids, but also tocopherol. The exact mechanism of the causation of these liver lesions is therefore still obscure.

# Notes on Contributors

DR. ERNEST BALDWIN is a University Lecturer in the Cambridge School of Biochemistry. He was educated at St. John's College, Cambridge, where he held a Fellowship from 1936 to 1941. He is a member of the Marine Biological Association of the United Kingdom, of the Biochemical Society, of the Society for Experimental Biology and of the Cambridge Philosophical Society. He has worked mainly on comparative biochemistry, especially on muscle, electric tissue, and the nitrogenous metabolism of invertebrates. During the war he was engaged in research on anthelmintics. He has played a leading part in developing the teaching of pure biochemistry to undergraduate science students at Cambridge and is the author of two textbooks: *An introduction to comparative biochemistry* (Cambridge University Press, 2nd ed., 1940) and *Dynamic aspects of biochemistry* (Cambridge University Press, 1947).

DR. MARJORY STEPHENSON is director of the Medical Research Council's Unit for Chemical Microbiology in Cambridge. Dr. Stephenson, who is a Fellow of the Royal Society, has worked for many years on problems of bacterial enzyme chemistry and is the author of *Bacterial metabolism*, the well-known textbook on the subject, as well as of a series of papers published mainly in the *Biochemical Journal*. The main trend of her work has been the study of bacterial enzymes, with a view to elucidating problems of growth and adaptation. She has recently been appointed Reader in Microbiological Chemistry in the University of Cambridge.

DR. E. F. GALE is a member of the scientific staff of the Medical Research Council and has worked in the Council's Unit for Chemical Microbiology at Cambridge for some years on the amino-acid metabolism of bacteria. He worked out the conditions necessary for the production of amines by bacteria and (with Epps) first obtained the amino-acid decarboxylases in a cell-free state; these investigations eventually led to the identification of pyridoxal phosphate as the prosthetic group of these enzymes. He is now studying the assimilation of amino-acids by bacteria and the effect of chemotherapeutic agents, particularly penicillin, on the processes involved. Publications: "Bacterial amino-acid decarboxylases" (*Advances in Enzymology*, 1946, 6, 1); *The chemical activities of bacteria* (University Tutorial Press, 1947); papers in *Biochemical Journal* and *Journal of General Microbiology*, etc.

DR. D. D. WOODS read biochemistry at Cambridge and worked there for a number of years on problems of bacterial metabolism in Dr. M. Stephenson's

unit. For part of this period he held a Beit Memorial Fellowship. In 1939 he joined the Medical Research Council Unit for Bacterial Chemistry (under Sir Paul Fildes) and in 1940 published his observations on the relation of *p*-aminobenzoic acid to the mode of action of the sulphonamides (*Brit. J. exp. Path.* 1940, 21, 74) which were the basis of an hypothesis concerning the fundamental biochemical action of these drugs which is now widely accepted. For the greater part of the war Dr. Woods was on the staff of the Microbiological Research Department, Porton. He is now Reader in Microbiology in the Department of Biochemistry, University of Oxford and is continuing his work on the biochemical aspects of sulphonamide action and related subjects. Dr. Woods is on the editorial staff of the *British Journal of Experimental Pathology* and the *Journal of General Microbiology*.

PROFESSOR R. A. PETERS has previously contributed to the Bulletin a paper on "The biochemical lesion in thermal burns" (*BMB* 688), with which a note on his work was published.

PROFESSOR R. H. S. THOMPSON was educated at Trinity College, Oxford, and Guy's Hospital Medical School. Holding the Adrian Stokes Travelling Fellowship, he worked from 1937 to 1938 in the Hospital of the Rockefeller Institute for Medical Research, New York. In 1938 he was awarded the Gillson Research Scholarship in Pathology by the Society of Apothecaries of London. Since 1938 he has been a Medical Fellow of University College, Oxford and Demonstrator in Biochemistry, Oxford. From 1939 to 1944 Professor Thompson was a member of the Extra-mural Research Team, Chemical Defence Research Department, Ministry of Supply, under the direction of Professor R. A. Peters, who also contributes a paper to this number (*BMB* 1198); and from 1944 to 1946 served as Major, RAMC, attached to the Australian Army. In 1946 he became Dean of the Medical School, Oxford University, and in October 1947 was appointed to the Chair of Chemical Pathology at Guy's Hospital Medical School, London. He is also Secretary of the Medical Research Council Conference on British Anti-Lewisite. Professor Thompson has worked with Professor Peters on pyruvate metabolism in vitamin-B<sub>1</sub> deficiency, and with Dr. R. J. Dubos on the nucleic acids of pneumococci. He has done much work on various applications of BAL, and on the action on cholinesterases of certain substances of interest in chemical warfare.

MR. M. V. TRACEY is a member of the biochemistry department of Rothamsted Experimental Station. He graduated from Cambridge University in 1940, where he had read biochemistry under Gowland Hopkins. After work on the manufacture and development of propellants for the Admiralty and on blood transfusion for the Ministry of Health he went to Rothamsted and worked on the proteases of green leaves. He is the author of a book on proteins at present in press.

MR. N. W. PIRIE studied under Hopkins in Cambridge; his first research there was on the chemistry and metabolism of sulphur compounds. Opportunities of collaboration with animal and plant pathologists in Cambridge led to research on antigens from *Brucella* and on plant viruses. This led to a general interest in large molecules of various types and to a tendency to doubt the usefulness of many of the concepts used in describing them. The biochemical department at Rothamsted, of which Pirie is head, is concerned with the isolation and characterization of the colloidal components of normal and virus-infected leaves. From this it is hoped that some understanding of the state of viruses in the cell and of their mode of multiplication will be gained.

PROFESSOR A. WORMALL is professor of biochemistry and chemistry in the University of London, at St. Bartholomew's Hospital Medical College. He graduated with honours in chemistry at Leeds in 1921, and was awarded his D.Sc. in 1930. He was demonstrator, and later lecturer, in biochemistry in the department of physiology at Leeds up to his appointment to the Chair at St. Bartholomew's in 1936. In 1928 he was awarded a Rockefeller Medical Fellowship by the Medical Research Council, and he spent a year with Landsteiner at the Rockefeller Institute studying some chemical problems of immunity. At the request of the Colonial Office he went to Uganda in 1930 to carry out investigations on human trypanosomiasis. These investigations were mainly concerned with the carbohydrate metabolism of sleeping-sickness patients, and with diagnostic tests for the disease; in particular, the red-cell adhesion test was suitably modified and found to be of definite practical value. Professor Wormall is specially interested in the chemistry of immunity, and in more recent years he has been using radioactive and stable isotopes for these studies. During the recent war, however, much of this work had to be put on one side in favour of more urgent mustard-gas problems. This mustard-gas work, started early in 1939, was later continued by a team under the leadership of

## NOTES ON CONTRIBUTORS

Professor Wormall as an extramural war investigation for the Ministry of Supply. In much of this work radioactive sulphur was used, and radioactive isotopic tracers are now being used in his laboratory for the study of immunochemistry and some general problems of biochemistry.

DR. KENNETH BAILEY is an authority on proteins and is particularly concerned with structural proteins connected with the contractility of muscle. He graduated at Birmingham and after three years of research on carbohydrates took up the study of proteins at Imperial College and later at Cambridge. In 1939 he was awarded a Rockefeller Fellowship to study physico-chemical aspects of proteins under Dr. E. J. Cohn of the Harvard Medical School. At present he holds an Imperial Chemical Industries Research Fellowship. His early work in collaboration with Professor W. T. Astbury led to a general formulation of the mechanism of denaturation and was applied to the large-scale production of artificial wools. Later, he worked on the chemical and enzyme properties

of myosin and on the nature of fibrinogen-fibrin and has recently elucidated the myosin-actin interaction. In addition, he has isolated a new crystalline, fibrous protein, tropomyosin, from the muscle fibril, and has also taken part in the preparation of pure yeast pyrophosphatase and crystalline hexokinase. Publications include two reviews on muscle proteins (*Recent Advances in Protein Chemistry*, 1944, 1, 289; *Annu. Rep. Chem. Soc.*, 1946, 43, 280).

DR. R. A. KERWICK is director of the Division of Biophysics at the Lister Institute, London, and collaborates with the Medical Research Council Blood Products Unit, which is also housed at the Lister Institute, in the preparation of human plasma products. His interests have always been associated with the physico-chemical aspects of protein behaviour, with special reference to ultracentrifuge and electrophoresis measurements and their correlation with specific biological activity. His studies have ranged over pathological human sera, therapeutic anti-

toxic sera, and the design of bulk protein fractionation procedures. Papers have appeared in the *Biochemical Journal* and the *British Journal of Experimental Pathology*.

DR. A. NEUBERGER is a member of the Scientific Staff of the Medical Research Council at the National Institute for Medical Research. He is Secretary of the Protein Requirements Committee of the MRC and a member of the Committee of Protein Requirements of Infants; he is also a member of the editorial board of the *Biochemical Journal*. Dr. Neuberger was awarded the William Julius Mickle Fellowship of the University of London for 1946-47. His research up to the war was concerned mainly with the structural chemistry of proteins, dissociation constants of amino-acids and chemistry of amino-sugars. Since the war he has become interested in the metabolism of amino-acids and problems of protein nutrition. Various papers by Dr. Neuberger have been published in the *Biochemical Journal*, *Journal of the Chemical Society*, and *Proceedings of the Royal Society*.

\* \* \*

IN previous volumes the Bulletin contained, in addition to the scientific symposium which occupied the greater part of each number, subsidiary sections of bibliographical and historical interest. Starting with the first number of Volume 5, the Bulletin has been clearly divided into two parts. The collective monograph on a special subject which had become the characteristic feature of the Bulletin now constitutes Part I. Part II contains miscellaneous articles on medical subjects of scientific, bibliographical, and historical interest. The book-review section is extended and there are, as before, sections devoted to historical notes, film-reviews, and lists of contents of current British medical and cognate periodicals. It is our intention that Part II should be a medium for extending the range of interest of each number of the Bulletin and for enhancing its continuity as a periodical.

## THE MEDICAL RESEARCH COUNCIL

### Its Origin, Constitution and Functions

F. H. K. GREEN M.D. F.R.C.P.

*Assistant Secretary, Medical Research Council*

The promotion of medical research on an organized scale has been accepted as a State responsibility in Great Britain for more than thirty-five years. The provision made by the State for this purpose is additional to the resources of universities and other independent foundations and institutions, but is itself substantial, amounting in terms of money expenditure in the current year to more than £770,000. These funds are administered by the Medical Research Council, a Government body though not, strictly speaking, a Government department. Like its sister organizations for industrial and agricultural research—the Department of Scientific and Industrial Research, and the Agricultural Research Council, respectively—the Medical Research Council is under the authority of a special Privy Council Committee of Ministers of the Crown. The Lord President of the Council—that is, of the Privy Council—is the Chairman of the Committee of the Privy Council for Medical Research and of the corresponding committees for scientific and industrial and agricultural research, and he is the Minister responsible to Parliament for the work of these three Government research bodies, an arrangement which assists effective co-operation between them.

#### Origin and Constitution

The Medical Research Council derives from the Medical Research Committee which was established in 1913 under the National Health Insurance Joint Commission to administer moneys provided for medical research under the National Health Insurance Act of 1911. This Committee had hardly had time to inaugurate its programme before it was confronted by the abnormal situation caused by the outbreak of the war of 1914-18. Co-operating closely with the Army Medical Service during that period, it promoted a large number of short-term studies relating to the treatment of wounds and injuries, to the etiology and treatment of tropical diseases, and to various other problems of military and civil hygiene, many of which have had permanent value. With the end of the war, and the passage of the Act of 1919 which established the Ministry of Health, there was a fundamental change in the administrative arrangements for the promotion of British government-aided medical research, one of the provisions of the new Act being to transfer this responsibility to a specially appointed Committee of the Privy Council. In 1920, accordingly, the former Medical Research Committee was reconstituted as the Medical Research Council under the statutory authority of the Committee of the Privy Council for Medical Research; it was granted a Royal Charter of

Incorporation and the funds for its work were thereafter provided directly from the Treasury in the form of a grant-in-aid approved yearly by Parliament, an arrangement which has persisted ever since. The Committee of the Privy Council for Medical Research consists, in addition to the Lord President as Chairman, of the Ministers in charge of the principal State departments concerned with questions of public health in Britain and the Empire overseas; the Minister of Health is Vice-Chairman, and the Secretary of the Medical Research Council for the time being is *ex officio* Secretary; this means, in effect, that there is direct contact between the Council and its Minister, the Lord President.

The Council itself consists nowadays of twelve members, three lay and nine scientific, with a Secretary and other administrative officers. The present Secretary is Sir Edward Mellanby, G.B.E., K.C.B., F.R.S., whose own researches on rickets and other health problems are well known. Members of the Council retire in turn at regular intervals, but the aim is to ensure that its scientific membership always comprises a body of distinguished experts with first-hand experience of research in clinical medicine and surgery, and in the more important of the fundamental sciences on which these are based, as well as in some of the specialities of medicine. The scientific members of the Council are appointed by the Privy Council Committee, after consultation with the President of the Royal Society (as representing independent scientific opinion in the country), and with the Council itself. Of the three lay members of the Council, one must be a member of the House of Lords and one a member of the House of Commons. The Council appoints its own Secretary, and its administrative and scientific staff.

#### Functions

While research into the nature and causes of disease, and into improved methods for its prevention, diagnosis and treatment, naturally forms an extremely important part of the research programme of the Medical Research Council, that programme is of very much wider scope. It deals also with the fundamental sciences of medicine—physiology, biochemistry, genetics and the like; with problems of nutrition and of the maintenance of general human well-being, mental as well as physical; and with the normal and abnormal physiological and psychological reactions of the human being to his work and environment. It may deal, in fact, with almost any question involving the "human factor".

To advise it on the promotion of research in particular branches of medical science, the Council has the help of a large number of expert technical committees which it has itself appointed from time to time. The terms of reference of these different committees cover a very wide range of subjects; some of them are appointed on a short-term basis, to direct research on a single problem or group of problems, and are discharged on the completion of that task; others, such as the Accessory Food Factors Committee and the Chemotherapy Committee, are standing committees which assist the Council in the organization of long-term inquiries over an extensive field. Committees set up between 1939 and 1945 to direct research on urgent war problems included the Military and Royal Naval Personnel Research Committees and the War Wounds Committee; others were the Malaria Committee, the Jaundice Committee, the Penicillin

Clinical Trials Committee, the Committee on Tuberculosis in Wartime, and there were many more. Two examples of special interest at present are the Committee on the Medical and Biological Applications of Nuclear Physics (the medical by-products of modern atomic research), and the Colonial Medical Research Committee, the latter appointed jointly by the Council and the Colonial Office to direct work on nutritional and other questions affecting the health and well-being of colonial peoples, including, of course, the study of tropical diseases. In promoting research on problems of industrial welfare and efficiency the Council has the advice of its Industrial Health Research Board, and of special committees on Occupational Medicine, Occupational Physiology, Occupational Psychology, etc.

The Council itself meets about nine times a year, to survey and plan its programme, to discuss questions of policy, to consider requests from Government departments and other bodies for assistance in dealing with health and other "human" problems within their sphere, to receive the recommendations of its various expert committees, to review and, where necessary, increase the appointments to its staff, and to deal with applications from independent workers for financial aid in their researches. To assist in planning and directing investigations undertaken at the request of the Ministry of Health or other Government departments, the Council has usually appointed *ad hoc* committees, including representatives of the departments concerned. One such body which is very active at present is the Committee on Industrial Pulmonary Disease, originally appointed in response to requests from the Home Office and the Mines Department, and reconstituted in 1945 by arrangement with the newer Ministry of Fuel and Power; this Committee has sponsored a long-term programme of research, now being widely extended, on the problem of occupational lung disease in coalminers and other industrial workers.

In addition to having full executive control of its Parliamentary grant-in-aid, the Council is empowered by its Charter to accept and administer charitable benefactions by gift or bequest for the support of medical research. Its constitution also enables it to collaborate freely with other official or non-official organizations, either in Britain or abroad, which have functions similar to its own. Examples of such non-official organizations in Britain are the Lister Institute of Preventive Medicine, the Imperial Cancer Research Fund, the British Empire Cancer Campaign, the Wellcome Foundation and the Nuffield Foundation. An overseas body which has given generous help and co-operation to the Council in many different ways is the Rockefeller Foundation of New York.

#### National Institute for Medical Research and Associated Establishments

The Council's administrative headquarters is at 38 Old Queen Street, London, S.W.1, and its central research laboratories comprise the National Institute for Medical Research, at present situated at Hampstead, London, with associated Farm Laboratories and a special building for nutritional research, at Mill Hill, a few miles away. The institute at Hampstead—a former hospital, which was acquired by the Medical Research Committee in 1914—has become inadequate for growing needs, and it is hoped

within the next two years to transfer its work to a new and much more commodious building on the Council's land at Mill Hill. The external structure of this new building was completed shortly before the war of 1939–45, and every effort is now being made to complete its internal equipment with minimum delay. Only laboratory research is done at the National Institute, the Council's programme of clinical investigations being carried out at other centres, as will be shown presently. Nevertheless, though much of the research work at the Institute is necessarily of a fundamental nature, a substantial part of it has an immediate bearing on clinical problems, and numerous field-studies in hospitals and elsewhere have been organized from the Institute; an instance is the new attack launched in 1946 on the etiology of the common cold; this is being carried out in a special unit at the Harvard Hospital, Salisbury, maintained jointly by the Council and the Ministry of Health. The research programme of the National Institute is a very wide one, divisible into the broad categories of physiology, pathology (including bacteriology, virus diseases and immunology), pharmacology, chemotherapy, biochemistry, endocrinology, and physics in relation to biological research. Diseases recently under intensive study there have included influenza, malaria and, during the war, the typhus fevers. A special responsibility of the Institute is the maintenance of standards of activity and purity for certain drugs, hormones, vitamin preparations and antitoxins, both in fulfilment of statutory obligations of the Council in the United Kingdom and, in many instances, on behalf of the World Health Organization (formerly the Health Organisation of the League of Nations). Sir Henry Dale, O.M., G.B.E., F.R.S., was the first Director of the National Institute; he was succeeded, on his retirement in 1942, by Dr. C. R. (now Sir Charles) Harington, F.R.S.

#### Clinical Research

Clearly, in any organized programme of medical research, prominence must be given to the study of problems of disease and injury as they are seen in patients—that is, to clinical investigations in hospital wards and outpatient departments. The Council has not established a special research hospital, deeming it preferable to take advantage of the available facilities and freer supply of clinical material at existing hospitals and the valuable opportunities to recruit and train new investigators which are provided by the day-to-day contact of research-workers with undergraduate and postgraduate students at academic centres. In conformity with this policy, the Council has for long maintained, wholly or in part, special units for clinical research at two London teaching-hospitals and at the National Hospital for Nervous Diseases, Queen Square, London. The oldest of these establishments is the Department for Clinical Research at University College Hospital, and it was here that the late Sir Thomas Lewis, F.R.S., carried out much of his famous work on diseases of the heart and blood-vessels. With the expansion of the Council's programme, the number of its special research groups dealing with clinical and other problems has been greatly increased in recent years; the Table appended shows the Council's chief existing research-establishments, other than the National Institute for Medical Research. The arrangement between the Council and the institution housing

**PRINCIPAL RESEARCH ESTABLISHMENTS OF THE MEDICAL RESEARCH COUNCIL OTHER THAN THE NATIONAL INSTITUTE FOR MEDICAL RESEARCH AND ASSOCIATED ESTABLISHMENTS (SPRING 1948)**

<i>Subject</i>	<i>Establishment</i>	<i>Place</i>	<i>Present Director of Unit or Department; or Head of Research Group</i>
General medicine	Department of Clinical Research	University College Hospital, London	E. E. Pochin, M.D., F.R.C.P. (salary provided by Rockefeller Foundation)
General medicine	Clinical Research Unit	Guy's Hospital, London	R. T. Grant, O.B.E., M.D., M.R.C.P., F.R.S.
Medicine (including nutritional and paediatric studies)	Department of Experimental Medicine	Cambridge University (with temporary field-research unit at Wuppertal, Germany)	Prof. R. A. McCance, Ph.D., M.D., F.R.C.P., F.R.S.
Diseases of the nervous system	Neurological Research Unit	National Hospital, Queen Square, London	E. A. Carmichael, C.B.E., M.B., F.R.C.P.
Problems of ear disease and deafness	Otological Research Unit	National Hospital, Queen Square, London	C. S. Hallpike, M.B., F.R.C.P., F.R.C.S.
Problems of vision	Vision Research Unit	Central London Ophthalmic Institute, Judd Street, W.C.1	H. Hartridge, M.D., F.R.S.
Treatment of cancer	Radiotherapeutic Research Unit	Hammersmith Hospital, London	Miss C. A. P. Wood, M.R.C.P., D.M.R.E. (half-time)
Industrial diseases and poisoning	Department for Research in Industrial Medicine	London Hospital	D. Hunter, M.D., F.R.C.P. (part-time)
Industrial health hazards, including injuries and skin diseases	Industrial Medicine Research Unit	Birmingham Accident Hospital and Rehabilitation Centre	J. R. Squire, M.B., M.R.C.P.
Burns	Burns Research Unit	Birmingham Accident Hospital and Rehabilitation Centre	" "
Industrial pulmonary disease	Pneumokoniosis Research Unit	Llandough Hospital and other centres, Cardiff	C. M. Fletcher, M.D., F.R.C.P.
Actions of drugs in man	Clinical Chemotherapeutic Research Unit	Glasgow University and Killearn Hospital	J. Reid, M.D., M.R.C.P. (part-time)
Clinical aspects of endocrinology	Clinical Endocrinology Research Unit	Edinburgh University and Royal Infirmary	(At present directed by a Committee)
Nutrition	Human Nutrition Research Unit	National Hospital, Queen Square, London, and London School of Hygiene and Tropical Medicine (with associated establishment in tropical Africa)	Prof. B. S. Platt, C.M.G., M.B., Ph.D.
Nutrition (vitamin studies)	Group for Research on Nutrition	Lister Institute of Preventive Medicine, London	S. S. Zilva, D.Sc.
Nutrition (vitamin studies)	Dunn Nutritional Laboratory	Cambridge University	L. J. Harris, Sc.D.
Dental disease	Dental Research Unit	King's College Hospital, London	J. D. King, Ph.D., L.D.S.

a particular establishment varies from case to case, but the Council usually provides the medical and other scientific workers and the research expenses, the institution supplying accommodation and, in the case of the clinical units, the cost of feeding and nursing the patients. A statistical-research unit has been part of the Council's organization since the earliest days of its work; the unit is housed in the Department of Medical Statistics at the London School of Hygiene and Tropical Medicine, the Director of the unit, Professor A. Bradford Hill, himself giving part-time service to the Council.

Apart from its research establishments in Great Britain,

the Council during the war despatched a number of field-research units overseas to carry out intensive investigations of health problems affecting the Fighting Forces. This principle is being extended in peacetime by the occasional appointment of special research groups to investigate health problems of importance to the Colonial Empire, at suitable centres abroad.

At the National Institute for Medical Research, at all the research centres listed in the Table, and at many others, the Council employs a whole-time scientific staff, appointed on either a permanent or a temporary basis. The large majority of the medical men or women directing, or working

<i>Subject</i>	<i>Establishment</i>	<i>Place</i>	<i>Present Director of Unit or Department; or Head of Research Group</i>
Bacterial chemistry	Bacterial Chemistry Research Unit	Lister Institute of Preventive Medicine, London	Sir Paul Fildes, O.B.E., M.B., F.R.S.
Bacterial chemistry	Group for Research in Chemical Microbiology	School of Biochemistry, Cambridge University	Miss M. Stephenson, Sc.D., F.R.S.
Cell metabolism	Cell Metabolism Research Unit	Sheffield University	Prof. H. A. Krebs, M.D., F.R.S. ( <i>part-time</i> )
Problems of blood grouping	Blood Group Research Unit	Lister Institute of Preventive Medicine, London	R. R. Race, M.R.C.S.
Preparation of blood derivatives	Blood Products Research Unit	Lister Institute of Preventive Medicine, London	A. N. Drury, C.B.E., M.D., F.R.S. ( <i>Hon. Director</i> )
Problems of transfusion	Blood Transfusion Research Unit	Postgraduate Medical School of London	P. L. Mollison, M.D., M.R.C.P.
Chemotherapy of malaria	Group for Research in Chemotherapy	Molteno Institute, Cambridge University	Miss A. Bishop, Sc.D.
Toxicology (with special reference to industry)	Toxicology Research Unit	Chemical Defence Experimental Station, Porton	J. M. Barnes, M.B.
Electromedical studies	Electromedical Research Unit	Ministry of Pensions Hospital, Stoke Mandeville, Bucks	R. B. Bourdillon, C.B.E., M.C., A.F.C., D.M.
Biophysics	Biophysics Research Unit	King's College, London	Prof. J. T. Randall, D.Sc., F.R.S. ( <i>Hon. Director</i> )
Medical problems of nuclear physics (including research on health hazards)	Radiobiological Research Unit	Atomic Energy Research Establishment, Harwell	J. F. Loutit, D.M., M.R.C.P.
Molecular structure of biological systems	Unit for Research on the Molecular Structure of Biological Systems	Cavendish Laboratory, Cambridge University	M. F. Perutz, Ph.D.
Industrial physiology	Groups for Research in Industrial Physiology	London School of Hygiene and Tropical Medicine	(i) T. Bedford, D.Sc. (ii) H. C. Weston, F.I.E.S.
Occupational psychology	Applied Psychology Research Unit	Cambridge University	Prof. Sir Frederic Bartlett, C.B.E., M.A., F.R.S. ( <i>Hon. Director</i> )
Occupational psychology	Group for Research in Industrial Psychology	Manchester and elsewhere	S. Wyatt, D.Sc.
Psychological and other "human" problems of the building industry (in relation to post-war reconstruction)	Group for Research on the Building Industry	Birkbeck College, London	Prof. C. A. Mace, M.A., D.Litt. ( <i>Hon. Director</i> )
Medical statistics	Statistical Research Unit	London School of Hygiene and Tropical Medicine	Prof. A. B. Hill, D.Sc. ( <i>part-time</i> )
Social medicine	Social Medicine Research Unit	Central Middlesex County Hospital	J. N. Morris, M.R.C.P., D.P.H., D.C.H.

in, these research establishments are whole-time servants of the Council who abstain from private practice. Among the subjects currently under study by members of the Council's staff at hospitals, university departments and other research centres outside the establishments listed in the Table are problems of disease in children, nutrition, clinical bacteriology, tuberculosis, chemotherapy, and the biological effects of radiation (with special reference to the treatment of cancer). Members of the Council's staff have pension-rights on retirement, which are provided through insurance policies to which both the Council and the member contribute.

#### Financial Aid to Independent Research Workers

While the greater part of the funds at the Council's disposal is devoted to the support of research by its own staff at the National Institute and elsewhere, an important fraction is, nevertheless, expended annually in the form of temporary grants made in aid of approved researches by entirely independent investigators at universities, hospitals and other institutions throughout the United Kingdom and, on occasion, overseas. These grants may be made variously for the personal support of the investigator on a whole-time or part-time basis, for the

provision of scientific or technical assistance to senior investigators, or for research expenses. Numerous investigations, at hospitals and elsewhere, by physicians or surgeons in practice are assisted by grants of one or more of these types. Where an application for a research grant comes within the field of interest of one of the Council's expert committees, the Council has the advice of the committee in considering it. An outstanding example of a research assisted by grants at a university centre during the war-years was the work by Sir Howard Florey and his colleagues at Oxford which led to the development of penicillin as a therapeutic agent. The grant system as a whole has produced a rich harvest of results of practical value.

Reference has been made above to the advantages, from the point of view of the recruitment and training of new research-workers in medical science, which are gained by the siting of most of the Council's clinical and other research establishments in academic centres. As a further aid to recruitment, the Council awards studentships for training in research methods to young graduates of special promise who are recommended for the purpose by the heads of the departments in which the training would be given. These studentships are tenable for a period of one year in the first instance, and are renewable up to a maximum of three years in all, subject to favourable reports from the supervisors of the work. One of the chief aims of the studentships is to make it possible for young men and women to contemplate, and display their fitness for, research careers who otherwise might be prevented by economic factors from doing so. Apart from these training studentships, which are tenable in the United Kingdom, the Council awards certain travelling fellowships to enable suitably qualified British workers to undertake periods of study and research at centres abroad. It has for long acted as the agent in Great Britain of the Rockefeller Foundation of New York, by awarding the travelling medical fellowships for British workers generously provided by that body, and it has its own series of travelling and research fellowships in tuberculosis, provided from the special benefaction in memory of Dorothy Temple Cross, of which it is the trustee.

### Reports and Publications

Before the war the Council had to submit annually to Parliament a Report on its work, which was published. The latest of these Reports to be issued was that for 1938-39. The series was interrupted by war conditions, but the continuity of the narrative has been resumed with a six-year Report, reviewing the Council's many activities during the war-period, which has just been published (Spring, 1948)<sup>1</sup>. All the Council's publications are printed and sold by His Majesty's Stationery Office. Best known among them is the series of green-covered Special Reports, on a diversity of medical subjects, of which more than 260 have been issued. Others deserving special mention here are the seventeen War Memoranda, giving up-to-date advice on practical problems (such as the medical uses of sulphonamides), which were issued by the Council between 1939 and 1946, and the series of reports dealing with problems of industrial hygiene and efficiency which have been produced under the authority of the Council's Industrial Health

Research Board. The Council's series of practical Memoranda is being continued in peacetime as a medium for the publication chiefly of summaries of existing knowledge, and the findings of *ad hoc* investigations. The results of the great majority of the researches supported by the Council are, however, reported directly by the investigators concerned, in papers contributed on their own initiative to medical and other scientific journals.

A *Bulletin of War Medicine*, consisting of abstracts and review-articles covering a large proportion of the contemporary medical and surgical literature from Allied and enemy countries, was produced by the Council from September 1940 till August 1946, with the help of the Bureau of Hygiene and Tropical Diseases.

### Other Activities

In addition to its primary task of promoting and supporting medical research, the Council during the war-period undertook a number of special executive functions on behalf of the Ministry of Health, with which it always maintains close co-operation. Thus it was in large measure responsible for organizing the Emergency Blood Transfusion Service for air-raid casualties in the greater London area, and it established four depots near London for the collection and storage of blood for transfusion, the staffs of which managed effectively to combine with their routine duties the making of substantial new contributions to knowledge of their subject. The Council also established units for serum drying and blood grouping at Cambridge during the war, the former of which, under the direction of Dr. R. I. N. Greaves, did interesting pioneer work on new methods of drying and preserving proteins, and the latter, under the late Dr. G. L. Taylor, successfully followed up and extended the American discovery of the Rh factor and its practical significance in blood transfusion and in paediatrics; the Blood Group Research Unit is being continued under the direction of Dr. R. R. Race at the Lister Institute, London (see Table). Moreover—and this, too, has proved a development of more than ephemeral significance—the Council in 1939 set up and administered, on behalf of the Ministry of Health, an Emergency Public Health Laboratory Service to augment the existing public-health services of the country in combating epidemics of infectious disease such as were likely to arise from the abnormal conditions of war, and to keep a constant watch for any suspected instance of "bacterial sabotage". While the Service did not, in the event, have any example of "bacterial sabotage" to contend with, it proved so notably successful in elucidating and restricting outbreaks of infectious disease and bacterial food-poisoning during the war that it is being extended in peacetime as the framework of an organization for carrying out nation-wide investigations of problems of public health and epidemiology. At the request of the Government, the Council accordingly agreed to administer the peacetime Public Health Laboratory Service on behalf of the Ministry for an initial period of five years. Statutory authority for the Service has been provided in the National Health Service Act of 1946.

Earlier in this article it was mentioned that one of the functions of the Council at its periodical meetings is to "survey and plan its programme". It should be emphasized, however, that long-term planning, save in very broad outline (as by the appointment of a committee or establish-

## BRITISH BIOCHEMISTRY

A. R. TRIM B.A. Ph.D.

*School of Biochemistry  
University of Cambridge*

In Britain, biochemistry was an early and vigorous outgrowth from modern physiology as it developed under the leadership of men like Sir Michael Foster. Foster (1924) was a firm believer in the importance of the study of the history of his subject; and in the first of his Lane Lectures on "The History of Physiology", delivered in San Francisco in 1900, he expressed that belief in the following words:

... What we know and what we think ... is a stream which flows by us and through us, fed by the far off rivulets of long ago. As what we think and say today will mingle with and shape the thoughts of men in the years to come, so in the opinions we are proud to hold today, we may, by looking back, trace the influence of the thoughts of those who have gone before ...

Our knowledge of history will reveal "... which of the thoughts of today are in the direct line of progress ...". This alone is sufficient reason for our application to a profound and detailed study of the history of British biochemistry.

A number of books on specialized biochemical subjects

provide us with specific examples of the power of the historical approach, but there has been nothing resembling a full account of the growth of the subject. Thus it is with hesitation that one attempts to sketch its history in a few pages. It is difficult to single out the contribution of one nation from the essentially international progress of science. However, even the most superficial consideration reveals that, in the biochemical field, Great Britain has contributed generously in terms of ideas, technical methods and hard work, the three essential components of creative scientific activity.

### *One Hundred Years Ago*

In July 1947, the Chemical Society celebrated its centenary. A hundred years ago biochemistry in Britain was in its embryonic stage. At home, formative influences, such as the work of Thomas Graham, first President of the Chemical Society, were developing. Abroad, Liebig in Germany, and Pasteur and Claude Bernard in France, were leading the world in establishing the basic principles of the subject. Development in Britain was comparatively slow up to 1900, and British biochemistry must be said to be essentially a twentieth-century phenomenon.

The chemical activities of living creatures have excited the interest of the natural philosopher from the earliest days, and led him to many significant observations. In 1772 Joseph Priestley showed that green leaves produce oxygen, the first important observation in connexion with photosynthesis. In 1810 Wollaston discovered the sulphur-containing amino-acid cystine, so-called because he found it in urinary calculi. However important, these discoveries did not constitute part of a connected scientific discipline. The present vigorous growth of the subject had its serious, organized beginnings in the period towards the end of the nineteenth century when the rationalization of medicine was taking place. This movement brought human physiology to maturity as an independent science, after it had

## MEDICAL RESEARCH COUNCIL

*Continued from page 356*

ment to carry out research over a considerable field), is rarely possible in medical science; the discovery of a preventive or cure for a particular disease is nearly always opportunist, depending upon the unpredictable occurrence of new clues for investigation, and upon the availability of research workers with the right type of knowledge and imagination to follow them up. Similar opportunist factors largely determine the range of the Council's research programme at any given time, and the number and staffing of its research establishments, though these are occasionally set up on an *ad hoc* basis to examine a particular health-hazard calling urgently for attention. Fleming's original work on penicillin was a good example of an opportunist investigation, arising in the course of studies of quite a different kind; on the other hand, the American discovery of streptomycin resulted from a "planned" attempt to find an antibiotic which would be therapeutically effective against the penicillin-resistant gram-negative microbes, though its still more remarkable action in certain forms of tuberculosis must have come as an agreeable surprise to its discoverers. Sometimes a long-term programme of "academic" research in physiology or biochemistry may itself lead suddenly to a discovery of immediate clinical value; while, as has been seen recently, the practical application of fundamental discoveries in the physical sciences may provide

new and totally unexpected vistas of exciting exploration in biology and medicine. Thus, the finding that radioactive isotopes of the elements can be produced artificially and, while behaving chemically exactly like the stable elements, may be readily traceable in the living body by virtue of their radioactivity, has supplied a method of fascinating promise for investigating the detailed chemistry and physiology of vital processes, as also has the use of naturally-occurring, non-radioactive isotopes as "tracers" by means of mass-spectrography. With these new research weapons of unforeseeable range, with the record of practical achievement during the last decade, and with the recent advances in chemotherapy, in bacterial chemistry and the study of microbic antagonism to provide embarkation points for further voyages of discovery, the prospects for medical research are brighter now than at any previous time. It is to be hoped that the free co-operation and exchange of scientific information established between medical scientists of the Allied nations during the war may be extended on an international scale for the still more rapid advancement of knowledge aimed at increasing human health and well-being in the years to come. It will be a task of the Medical Research Council to assist such co-operation to the fullest extent possible and to ensure that, so far as Great Britain and the Colonial Empire are concerned, the opportunities of the coming years are used to good effect.

functioned for a long period as a minor appendage of Anatomy. Biochemistry began then as a lesser aspect of physiology, but developed rapidly to play its present leading role.

The preponderant influence of medicine has remained a feature of biochemistry in this country. Although agriculture provides a vastly richer source of fascinating problems, it has had a much smaller influence. It may be significant that the decline of British agriculture had already set in before biochemistry had begun its vigorous development.

The advance of biochemistry depended primarily upon the enormous edifice of organic chemistry built mainly by the Germans during the last century. It is a disadvantage, perhaps still felt, that we in this country were late in recognizing this fact. As late as 1913, the late Sir Frederick Gowland Hopkins, in his presidential address to the Physiological Section of the British Association, found it necessary to reiterate the appeal made by Justus Liebig to the Chemical Section of the same organization in 1837, pleading for the closer integration of organic chemistry and biology. Today we are able to look back on many achievements based on that lesson. However, this alone would not have given us modern biochemistry, which, rightly, is concerned not mainly with the analysis and synthesis of substances of biological importance, but with the manner in which living organisms achieve chemical changes.

This brings us into the field of colloid chemistry and catalysis. About the middle of the last century, Thomas Graham characterized the colloidal state, and his colleague, Sidney Ringer, investigated the balanced activities of inorganic constituents in regulating energy discharges in living cells. Ringer made his observations long before Arrhenius put forward his Ionic Theory. It is an interesting sidelight on the narrow outlook of many scientists of the time that Arrhenius was unaware of how Ringer's observations bore eloquent testimony to the correctness of the ionic concept.

Physical chemistry provided one of the most delicate and successful tools used in biochemistry. Thudichum, Archibald Garrod, MacMunn and F. G. Hopkins, of the developing school of British biochemists, all used it to make observations of the first importance, before the end of the nineteenth century. Among the many brilliant observations of the ill-fated MacMunn (1886) was the discovery in 1886 of "myohaematin" or "histohaematin"—the substance now better known as cytochrome. This observation did not attract the attention it deserved because of the attacks of the famous continental biochemist Hoppe-Seyler, who did not accept it. MacMunn was so discouraged that he gave up his researches. Hopkins used the spectroscope in his classical work on the pterine pigments in butterfly wings.

Archibald Garrod was one of the first to achieve that revolution in thought by which metabolism came to be considered in terms of enzyme-catalyzed paths rather than as a gross process of combustion. He was the father of biochemical genetics, and it is only now that his views are producing a rich harvest in the work of the American school led by G. W. Beadle and E. L. Tatum. It is to the credit of a number of British workers that they carried this line of development forward during the long interim period. Prominent among them were V. A. Onslow, Mrs. Onslow,

J. B. S. Haldane and R. Scott-Moncrieff, all of whom worked in Hopkins' laboratory.

It is not possible to pass to the twentieth century without mentioning Thudichum, a prominent contemporary of Garrod's. Thudichum gave us the first firm chemical data on a number of the constituents of nervous tissues: he founded the chemistry of the brain.

#### *Hopkins, Harden and their Collaborators*

Gowland Hopkins dominated the development of biochemistry for the next forty years. By 1900 he had contributed his elegant work on the pterine pigments. In 1898 he and Pinkus had developed a greatly improved method for the crystallization of egg-albumin. In 1901 he and S. W. Cole isolated the amino-acid tryptophan from a tryptic digest of casein. Thus within two years he participated in two major contributions to protein chemistry. Then followed his nutritional studies, which established the nutritional importance of tryptophan and led to his discovery of the accessory food substances—the vitamins.

Hopkins inspired many lines of work now actively pursued all over the world. In some of them he conducted the classical experiments himself. The modern concept of the metabolic process directly concerned with energy production by working muscle, dates back to the work of Walter Fletcher & Hopkins in 1907. They confirmed previous observations that, when a muscle is made to contract in the absence of oxygen, lactic acid is produced. They also showed that the lactic acid is removed and glycogen reappears when the muscle is allowed to resume oxidative metabolism. This provided the essential idea of the muscle-cycle and of other glycolytic systems.

At about the same time Harden and his collaborators at the Lister Institute in London were working on the chemistry of the fermentation processes. This work was to merge eventually with the developments of Hopkins and Fletcher and in particular with the contributions of the German-led school in Europe, in the great burst of advances in our knowledge of the processes of glycolysis, which took place after the first World War.

In 1897 Buchner, in Germany, had shown that an extract of crushed yeast, from which all intact cells had been removed, retained the capacity to ferment sugars. Harden and Young studied this cell-free fermentation process and showed that the extract converted certain sugars to fructose diphosphate. This discovery ranks with the greatest in the history of the subject. Besides showing the importance of the phosphate esters in metabolism, Harden & Young (1904) were the first to demonstrate the existence of a co-enzyme: a heat-stable, dialyzable substance needed to activate an enzymic system. In 1904 they showed that such a substance, which they called co-zymase, now known as co-enzyme I, was essential in the yeast fermentation process.

Later, Robison, a pupil of Harden, discovered hexose monophosphate. Also, through a chance observation, he was able to show that the phosphate esters are concerned in the formation of calcium phosphate in calcifying tissues. In 1927, Eggleton and Eggleton, working at University College, London, showed that a new form of organic phosphate was involved in glycolysis. This was named phosphagen. It proved to be the substance, phospho-creatine, which had been isolated from muscle by the Americans Fiske and Subbarow in the same year.

These advances, combined with new knowledge of cellular oxidation-processes, marked the opening stages of the tremendous development in the study of cellular metabolism which took place between the two wars. In Britain, a large part of the work was concentrated in Hopkins' laboratory. Later it grew up in other centres mainly under the guidance of his former pupils, R. A. Peters at Oxford and H. A. Krebs in Sheffield.

The realization of the importance of carriers in biological oxidation processes began in 1921 with Hopkins' isolation of glutathione. This was followed in 1925 by Keilin's confirmation of MacMunn's discovery of cytochrome and his demonstration of its components and their role in cellular oxidation. M. Dixon, D. E. Green, Keilin again and many other workers in the Cambridge school contributed a mass of information on the nature of oxidation paths in the cell.

### *Bacterial Chemistry*

In the same school J. and D. M. Needham were studying the glycolytic systems in mammalian striped muscle and other tissues. J. H. Quastel and Marjory Stephenson were laying the foundations of the study of bacterial metabolism, using washed suspensions of bacteria. Since that time Quastel's interests have extended to a diversity of fields. The traditional study has been carried on by Stephenson and her school with a regular series of important discoveries. Stephenson's studies have been confined to dynamic aspects of the subject. The other famous group of bacterial chemists in this country, built up by Sir Paul Fildes and B. C. J. G. Knight at the Middlesex Hospital in London, devoted its attention to the nutritional requirement of bacteria and added a great deal to our understanding of vitamins and the nature of parasitism. The high-light of the work of this school was Woods' (1940) observations on the nature of the antibacterial action of the sulphonamides.

R. A. Peters, who has held the chair of biochemistry at Oxford for many years, has contributed much to the science, both as a philosopher and as a practical man. He was one of the first to link a vitamin with a metabolic process (Peters & Thompson, 1934) by showing that vitamin B<sub>1</sub> has a co-enzymic effect in the oxidation of pyruvate in brain. A recent outstanding achievement of his school was the production of BAL (British Anti-Lewisite).<sup>1</sup>

H. A. Krebs is the author of a great deal of important work on cell-metabolism. He is probably best known for his work on mammalian urea-production via the so-called ornithine cycle, or Krebs urea cycle (Krebs & Henseleit, 1932), and for his work (Krebs & Johnson, 1937) demonstrating the function of tricarboxylic acids in cell-metabolism.

Like Krebs, J. H. Quastel has produced a large volume of work on cell-metabolism. One of his most fruitful contributions was his demonstration (Quastel & Wooldridge, 1928) that malonate inhibited the oxidation of succinate by the enzyme succinic dehydrogenase. The degree of inhibition depended on the relative concentrations of the substrate (succinate) and the inhibitor (malonate). This phenomenon was called competitive inhibition. The principle was invoked by Woods to explain the competition

between *p*-aminobenzoic acid and sulphanilamide in their effect upon the growth of bacteria. Sulphanilamide prevents growth, but if *p*-aminobenzoic acid is present the amount of growth increases roughly in proportion to its concentration. Competitive inhibition has become one of the principal concepts of modern chemotherapeutic theory.

### *Biological Organic Chemistry*

The advances which have been described show the very great importance of organic chemistry in the development of biochemistry. However, there is a great tradition of biological organic chemistry in this country which has developed on rather different lines from those already described. The difference between the two traditions is one of emphasis, and each has contributed to the growth of the other.

One of the achievements of organic chemistry arising out of the work of Hopkins was C. R. Harington's synthesis of glutathione (Harington & Mead, 1935). Harington is an outstanding representative of the school of biochemistry built by George Barger. Barger studied chemical aspects of pharmacology, chemotherapy, hormones and vitamins. Harington and he were responsible for the classical work on the hormone thyroxine. In 1926 Harington (1926a) was successful in isolating it from thyroid glands. Shortly afterwards he established its chemical structure (1926b). The work was brought to a triumphant conclusion by the synthesis of thyroxine (Harington & Barger, 1927).

During the course of this century Barger achieved many syntheses and characterized numerous biologically-important substances. His greatest interest was in the so-called simpler natural bases. In 1905 he and Jowett came near to the synthesis of adrenaline. This synthesis was achieved by H. D. Dakin and simultaneously by continental workers. Barger collaborated with Sir Henry Dale in much work on the sympathomimetic amines. They isolated histamine from the animal gut and synthesized tyramine. Barger also synthesized methionine and carnosine and was associated with A. R. Todd and others in their work on the synthesis of vitamin B<sub>1</sub>. Barger was trained as a botanist as well as an organic chemist and in the course of his life made contributions to the chemistry of the alkaloids and glycosides.

Dale's most striking biochemical work was done in collaboration with H. W. Dudley (1927). These two workers were the first to isolate acetylcholine. Dudley was a brilliant worker who will be remembered for contributions such as the discovery of the enzyme glyoxalase (Dakin & Dudley, 1913), which converts methyl glyoxal to lactic acid.

In the last twenty years cyclopentenophenanthrene derivatives have been shown to have a variety of important biological functions as sex hormones, heart drugs, carcinogenic agents, bile acids, etc. British workers have played an essential part in this development. In 1932 Rosenheim & King put forward the idea that the sterols and bile acids were cyclopentenophenanthrene derivatives. This had a revolutionary effect and led to the rapid solution of the structure of many representatives of the above types of compounds. Prominent among the workers in this field were the British chemists Cohen, Cook, Dodds, Hewett and Kon.

<sup>1</sup> [See also *BMB* 1198.—Ed.]

A little earlier Marrian (1930), working at University College, London, had isolated the important female sex hormone, oestriol, from pregnancy urine. This was his first outstanding success among his important studies of the chemistry of the sex hormones.

For many years J. W. Cook, Kennaway and their collaborators searched among the coal-tar products for those responsible for its carcinogenic effects. They isolated and identified many polycyclic hydrocarbons with carcinogenic properties. Others they synthesized. Cook and E. C. Dodds initiated the study of synthetic oestrogenic substances. They were able to show that the oestrogenic effect could be obtained with a wide variety of chemical substances. The same group of workers established the important connexion between the oestrogenic and carcinogenic effects.

The University of St. Andrews is famed for its school of sugar chemistry which grew up at the end of the last century under the leadership of Purdie and Irvine. Purdie developed a gentle method for the methylation of the hydroxyl groups of sugars, whereby it became possible to carry the study of sugar chemistry forward after it had reached an impasse. Purdie's method opened the way for the study of the ring-structure of the monosaccharides and the way in which they are joined together to form higher sugars. The leader of British sugar-chemistry today is Sir Norman Haworth. He was formerly at St. Andrews and now heads the chemistry school at Birmingham. In 1925 he demonstrated the pyranose ring structure in sugars. A number of his collaborators, led by E. L. Hirst (*Ault et al.* 1933), achieved the first successful synthesis of vitamin C.

Britain has contributed relatively little chemical work in the field of vitamins. Besides the synthesis of vitamin C, contributions have been made to the chemistry of vitamin D and vitamin B<sub>1</sub>. Rosenheim & Webster produced vitamin-D activity by irradiating phytosterols in 1925; in 1932 a team of workers, *Askew et al.*, were successful in isolating pure crystalline vitamin D<sub>2</sub> from irradiated ergosterol. The contributions of Todd, Bergel and their group to the synthesis of vitamin B<sub>1</sub> have already been mentioned.

Todd was a pupil of Sir Robert Robinson, the leading British organic chemist. Robinson is best known for his work on two widespread groups of organic compounds occurring in the plant kingdom, the alkaloids and the anthocyanins and flavones. He achieved his classical tropinone synthesis in 1917; in 1924 Pratt & Robinson synthesized the anthocyanidin pelargonidin; ten years later Robinson (1934) announced his method for the synthesis of the complete anthocyanin molecule.

#### *Plant-Biochemistry*

Although many able organic chemists in Britain have devoted themselves to the study of plant products, the British tradition in plant-biochemistry is not strong. The work of Raistrick and his colleagues on the constitution of many substances which are produced by the metabolic action of moulds upon simple sugars is a major contribution

to our understanding of plant metabolism. Schryver's small school at South Kensington did much work in the field of analysis and isolation of plant products. Schryver was succeeded by A. C. Chibnall, who has an international reputation for work in this field, in particular for his classical work on the chemical constitution of the plant- and insect-waxes and his contributions to our knowledge of the amino-acid composition of proteins.

Two important recent advances in plant-biochemistry have been due to British workers. In 1940 C. S. Hanes reported the biosynthesis of one component of starch, and in the same year R. Hill demonstrated the production of oxygen by isolated chloroplasts.

#### *Recent Developments*

R. Hill (1939) has had a long association with biochemistry in Britain. His early work on haemoglobin formed part of the impressive series of studies on the respiratory function of the blood which started in Cambridge before the first World War. Many famous names are associated with that work: Barcroft, Haldane, Keilin, Roughton and others.

It has not been possible to consider all the important biochemical developments which have taken place in Great Britain. No mention has been made of the influence of men like Sir William Bate Hardy, Benjamin Moore and Raphael Meldola. Hardy contributed most to the field of biophysics, which has not been given its due attention in this survey. Physico-chemical methods have been greatly developed by British workers during the last two decades. Very recently Martin & Synge (1941) developed the partition-chromatogram and immediately effected a revolution in the amino-acid analysis of proteins. They were able to make great advances towards the solution of the problem of the quantitative separation of the mono-amino-acids, which had baffled the organic chemist for decades. Astbury, Bernal, Crowfoot and others developed x-ray analysis and applied it to the elucidation of the structure of biological molecules such as the fibrous and crystalline proteins. Bernal settled the doubt as to the detailed structure of cholesterol by this means. Confirmation of his view came from the field of surface chemistry, which had been developed in this country by E. K. Rideal and N. K. Adam.

Recent achievements such as the production of British anti-lewisite and penicillin represent the highest fruit of the British tradition. Each of them is a more than full justification for the many lines of earlier work upon which they depended: microbiology, enzyme studies, organic chemistry and many others. With a very limited scientific personnel, Britain is now faced with the difficult task of deciding which of the many profitable fields of biochemical study open to us will be the most profitable. It is not the task of the writer to propose a solution here. It is sufficient to say that whatever the general lines of the future development in British biochemistry, we can confidently expect it to continue to produce some of the world's best and most original contributions.

## CHEMOTHERAPY: A JOINT CHAPTER IN THE HISTORY OF CHEMISTRY AND MEDICINE

JAMES WALKER, Ph.D. D.Phil. D.Sc.

*National Institute for Medical Research, Hampstead, London*

*Chemistry is an Art, whereby sensible bodies contain'd in vessels, (or at least capable of being contained therein and render'd sensible;) are so chang'd, by means of certain instruments, and especially fire, that their several powers, and virtues are thereby discover'd; with a view to the uses of medicine, natural philosophy, and other arts and occasions of life.*

H. Boerhaave

*A new method of chemistry*, translated by P. Shaw & E. Chambers, London, 1727, p. 51

The relationship between chemistry and medicine, so intimate at the present time, extends backwards through the centuries to the distant times when primitive man, in his efforts to mitigate the hardships of life, came to associate in his mind, in his folk-lore, and in his writings, the ingestion of certain crude vegetable drugs—mineral drugs came later—with the alleviation of some of his bodily ailments. The Ebers papyrus, which dates from about the 14th century B.C., is actually a text-book of materia medica and is believed to contain a reference to colchicine (Sharp, 1909), whose biological effects are still the subject of intensive study. The name of Galen (131–201 A.D.) is familiar to students

of the history both of medicine and of chemistry, and is preserved to us to this day in the term "galenical". Such was Galen's influence that his teachings held sway for over a thousand years, until the iconoclastic figure of Paracelsus (1493–1541) came upon the scene, introducing the "iatro-chemical" period, to be followed closely by Vesalius (1514–1564), the father of anatomy, and by Harvey (1578–1657), the father of physiology. To these three men we owe the foundations of modern medicine, which has advanced with ever-increasing vigour since their time, particularly during the past 100 years with the growth of our precise and intimate knowledge of chemistry and pharmacology, and the rise of microbiology. As a sign of the times, the oldest national chemical society in the world was founded in London in 1841 under the chairmanship of Thomas Graham, the father of colloid science, and recently celebrated the centenary of its foundation, the observance of the occasion having been postponed because of the war. In 1858 Kekulé and Couper crowned the work of Dalton and Frankland with the structural theory of organic chemistry and paved the way for synthetic organic chemistry in the modern sense. Pharmacology, too, was put upon a sure foundation about the same time by Buchheim who emphasized that "die Arzneimittellehre ist eine theoretische, d.h. erklärende Wissenschaft und hat die Aufgabe, uns die auf die Arzneimittel bezüglichen Kenntnisse darzubieten, durch welche die Richtigkeit unseres Urteils über ihre Brauchbarkeit am Krankenbett gefördert werden kann" (Schmiedeberg, 1912). Following upon these events are recorded the foundation of bacteriology by Pasteur and Koch, its systematization by Cohn, Lord Lister's zealous advocacy of antiseptics, and the study of toxins and anti-toxins (Roux; von Behring), which was placed on a precise quantitative basis by Ehrlich. The great advances in microscopy in the early part of the century made by Lord Lister's father, Joseph Jackson Lister, and later by Abbe, coupled with selective staining (Weigert; Ehrlich) and other improvements in microbiological methods, led to the discovery, towards the end of the century, of protozoal parasites as the causes of disease, the names of Manson, Laveran and Bruce coming readily to mind in that connexion. The position at the turn of the century was therefore that chemistry, pharmacology, microbiology and parasitology had severally made distinguished progress during the nineteenth century but no one science had markedly made its influence felt upon any of the others. It was therefore

a timely development when Ehrlich brought about a fusion and founded experimental chemotherapy, which embraced them all. Although he took a medical qualification Ehrlich did not take his ideas from medicine, supporting them with chemical knowledge, but conversely, to quote his own words (1909), "ich während meiner ganzen wissenschaftlichen Arbeit mich bemüht habe, das, was uns die Chemie lehrt hat, auch der Medizin nutzbar zu machen". In searching for substances which should be lethal to infecting parasites and yet harmless to the infected host, Ehrlich sought to apply what a life-time's study of the selective affinities of chemicals for cells had taught him.

### Chemotherapy of Protozoal and Spirochaetal Infections

#### Early Trypanocidal Dyes : Bayer 205

The successful development of chemotherapy as an experimental science depended upon the transmission of diseases to experimental animals and Laveran & Mesnil's demonstration (1902a) that trypanosome infections could thus be studied in mice provided Ehrlich with a convenient subject for study. With Shiga, Ehrlich (1904) showed that the dye trypan-red (I) had the effect which he sought but a more successful substance was found by Mesnil & Nicolle (1906) to be trypan-blue (II), which found practical application in piroplasmosis of domestic animals (Nuttall & Hadwen, 1909). A further substance studied by Mesnil and Nicolle was trypan- (or afridol-) violet (III) which, although not applied practically, is of great historic interest as being the first representative of the symmetrical urea type of drug, further developed in 1912 by Heymann (see Roehl, 1926a), who replaced the chromophoric azo-linkage by amide groups, thereby abolishing undesirable tinctorial properties and ultimately yielding Bayer 205 (germanin, suramin, Fourneau 309) (IV), one of the most remarkable, and probably the most complex, of drugs ever

synthesized. The lineal descent of Bayer 205 from trypan-blue is reflected biologically in the fact that trypanosomes which have acquired resistance to trypan-blue are also resistant to Bayer 205 (Leupold, 1924), acquired resistance to one compound being usually accompanied by resistance to chemically-allied substances only. Bayer 205, or suramin, to give it its non-proprietary pharmacopoeial name, is one of our most valuable drugs in the chemotherapy of sleeping sickness, being useful prophylactically and also for the treatment of established infections provided the central nervous system is not involved.

#### Arsenicals

Although inorganic arsenic had been used empirically for trypanosomiasis in domestic animals for some time (Braid, 1858; Livingstone, 1858) the results can be described, at best, as indifferent (Laveran & Mesnil, 1902b) and a marked advance was Thomas's demonstration (1905) in Liverpool that atoxyl was an effective agent in trypanosomiasis. Stimulated by this observation, Ehrlich & Bertheim (1907) proceeded to the elucidation of the correct constitution of atoxyl (V) and then to the development of salvarsan, which Ehrlich & Hata (1910) introduced for the treatment of syphilis, the causative agent having just previously been demonstrated by the zoologist Schaudinn. Shortly afterwards, neosalvarsan, or neoarsphenamine (VI), was introduced and, with one or two analogous derivatives of the same parent compound, constituted chemotherapy's greatest accomplishment for many years.

It was found that while atoxyl was active *in vivo* it was not active *in vitro* against trypanosomes and it was concluded that reduction in the body to the trivalent arsenoxide stage preceded trypanocidal action and, similarly, as there is a latent period of several hours before spirochaetes, or trypanosomes, are cleared from the blood of animals treated with the arsphenamines, it was again concluded that conversion to the arsenoxide precedes chemotherapeutic action (Voegtlin & Smith, 1920). Although the arsenoxide is considered to be the form in which the arsphenamines exert their spirochaeticidal action in the body, Ehrlich and Hata had rejected this substance (VII) as being too toxic for clinical use, but work in the last decade has clearly shown that it has as satisfactory a chemotherapeutic index as the arsphenamines. There is good evidence to show that the arsenoxide interferes with the turnover of sulphhydryl groups in the parasite and by this interference a vital metabolic reaction is stopped. Conversely, by competition with the thiol groups of the parasite, the addition of glutathione and certain other thiol compounds both *in vitro* and *in vivo* protected trypanosomes against the arsenoxide by combining reversibly with the latter. An elegant application of this affinity of thiol groups for arsenic is to be found in BAL (British Anti-Lewisite), 2:3-dimercaptopropanol<sup>1</sup>, in which it was argued that, by forming a ring with two adjacent thiol groups, a less readily reversed detoxication of the arsenic could be achieved (Stocken & Thompson, 1946). So far, therefore, out of the hundreds that have been studied, those arsenicals which have attained a place in clinical medicine are: the arsphenamines and mapharside (VII), which are used in syphilis; tryparsamide (VIII) and orsanine (IX),

<sup>1</sup> [See *BMB* 1198 in this number.—Ed.]

which are used in trypanosomiasis on account of the ease with which these drugs can penetrate into the central nervous system and so reach parasites inaccessible to Bayer 205; and carbarsone (X), which has received some application in amoebic dysentery along with the alkaloid emetine and the iodohydroxyquinolines.

### Antimonials

The use of antimony, the congener of arsenic in the Periodic System of the elements, has not developed to the same extent as that of the latter, due, in some measure, to intrinsic chemical disadvantages. Although Plimmer & Thomson (1908) found at the Lister Institute that rats infected with trypanosomes could be freed from parasites by tartar emetic (XI) and its sodium analogue, the most significant application of antimony in chemotherapy has been in kala-azar. In 1912, Vianna found that cutaneous leishmaniasis could be influenced by tartar emetic, and the introduction by Rogers (1915) of tartar emetic in India for the treatment of kala-azar replaced symptomatic treatment, which was practically invariably unsuccessful, by specific therapy. Since 1915, a number of pentavalent antimony compounds have received careful clinical trial in kala-azar, and Brahmachari's urea-stibamine, of which the main component is the symmetrical urea (XII) (Gray, Trevan, Bainbridge & Attwood, 1931), and neostibosan (XIII) have come into fairly wide use for the treatment of infections in India and China. On the other hand, mediterranean infections respond better to tartar emetic and fouadin (XIV). Many compounds of antimony with hydroxy acids have been tested for chemotherapeutic activity but, of these, only two, sodium antimony tartrate and its potassium analogue (tartar emetic), are used in medicine at the present time. Similarly, trivalent antimony compounds with phenols and mercaptans are well known. Of the former, fouadin (stibophen) came into extensive use in 1929 (Khalil

*et al.*) and partly displaced tartar emetic in the treatment of schistosomiasis, the latter having come into prominence for this purpose in 1918 (Christopherson). Still later, in 1936, anthiomaline was introduced by french workers but current opinion is divided as to the value of this drug.

### Diamidines

In considering the mode of action of Bayer 205, von Jancso & von Jancso (1934) considered that the drug interfered with the sugar metabolism of trypanosomes. It was known that hypoglycaemia occurs in experimental trypanosome infections, and that trypanosomes, furthermore, consume large amounts of glucose. The von Jancsos (1935; also Schern & Artagaveytia-Allende, 1936) therefore proceeded to an examination for trypanocidal activity in vivo of the synthalins—discarded several years previously after a brief but inglorious career as an oral substitute for insulin—and did indeed observe activity, but not because of any effect on sugar metabolism, since Lourie & Yorke (1937) showed synthalin to act directly on trypanosomes in vitro in high dilution. With the chemical collaboration of King (King, Lourie & Yorke, 1937), it was found that the guanidine groups of synthalin (XV) could be replaced by other groups, and, in particular, by amidine groups giving diamidines (XVI), which were yet more active and less toxic than the diguanidines. Later, it was found that the alkylene chain could be replaced by aromatic groups (King, Lourie & Yorke, 1938) and further development of this type in the May and Baker laboratories has led to stilbamidine (XVII), propamidine (XVIII) and pentamidine (Ashley *et al.* 1942). Like Bayer 205, these compounds are markedly active in the early stages of *T. gambiense* and *T. rhodesiense* sleeping sickness but their most fruitful application has been in kala-azar, in which antimony-resistant cases have responded, and in babesiasis in domestic animals (Yorke, 1944). Propamidine has also received some application as a topical antibacterial agent but marked toxicity is a disadvantage shared by these compounds.

### Phenanthridinium Compounds

In 1931, Morgan & Walls at Teddington began a comprehensive investigation of phenanthridine compounds based on the readily available 2-aminodiphenyl. Biological tests from time to time failed to reveal promising

activity until Browning and his collaborators encountered trypanocidal activity in quaternary salts from 3 (and 7) -amino-9-*p*-aminophenylphenanthridine derivatives (Morgan *et al.* 1938). Further investigation of this series has revealed substances with pronounced activity against the relatively resistant *T. congolense* infections (Walls, Browning, Calver & Leckie, 1945), and recently activity against *T. cruzi* has been detected (Walls *et al.* 1946), only one other drug (Bayer 7602 Ac) being notably active against the latter parasite, which is refractory to other classes of trypanocidal drugs.

It is of interest to note that the phenanthridinium compounds bear a distinct resemblance chemically to trypanocidal styrylquinolines, which were previously studied by Browning and Cohen with their collaborators (Browning, Cohen, Ellingworth & Gulbransen, 1926, 1929), as shown by the following formulae (XIX, XX) of highly active compounds in the respective series, the elimination of the -CH:CH- group being one which the chemist can envisage with equanimity:—

#### Antimalarials

The time-honoured use of quinine in the treatment of malaria is a genuine example of chemotherapeutic action and, beyond Ehrlich & Guttman's (1891) empirical trial of methylene blue, no further progress in the chemotherapy of malaria took place until a precise testing method (Roehl, 1926b) rendered the laboratory examination of drugs feasible. Plasmochin (pamaquin, XXI) was first elaborated (Roehl, 1926b), based, it is said, on Ehrlich's early methylene-blue experiment, and followed, a few years later, by atebrin (mepacrine XXII) (Kikuth, 1932), which is said to have been based not on methylene blue but on acriflavine, the Germans being impressed with Browning's exploitation of acriflavine during the first World War. Quinine and atebrin dominated the therapy of malaria until the entry of Japan into the late war rendered the former unobtainable, and an added stimulus was thereby given to the search for still further antimalarial drugs. Shaking themselves free from the tradition that antimalarial activity should be sought among derivatives of quinoline and acridine, Curd, Davey & Rose (1945) of Imperial Chemical (Pharmaceuticals), Ltd. accomplished a remarkably successful search with the ultimate production of paludrine (XXIII), which is the most versatile antimalarial drug yet discovered. Recent American work has revealed promising activity in resochin (XXIV), which may be regarded as being derived from mepacrine (XXII) by ablation of the methoxylated benzene ring, and a

homologue, sontochin; these two drugs were encountered initially in the I.G. laboratories but were not brought into full production by the Germans because of economic war-time difficulties.

#### Chemotherapy of Helminthiasis

Numerous locally acting drugs are known which will expel parasitic worms from the gastro-intestinal tract but it is doubtful if any of these compounds conform to the usual criteria of chemotherapeutic agents, and the lack of suitable experimental animals in which the infections can be maintained and studied has hampered research on the chemotherapy of helminthiasis. Within the past year, however, notable advances in the chemotherapy of filariasis have emerged from the use of a natural filarial infection of cotton rats for the routine examination of drugs. A number of compounds of the cyanine-dye type were first shown to be active in the cotton rat (Welch *et al.* 1947; Brooker & Sweet, 1947), and still more recently, marked activity has been discovered among piperazine derivatives, out of which hetrazan (XXV) has been selected for further study (Hewitt *et al.* 1947).

Miracil (XXVI), which was found to be active in experimental schistosomiasis, has proved disappointing in human clinical trials.

#### Chemotherapy of Bacterial and Virus Infections

##### Antibacterial Chemotherapy

In discussing antibacterial agents it is customary to think in terms of disinfectants, antiseptics and chemotherapeutic agents but, strictly speaking, the one type merges with the other in the order given and differences are relative ones depending upon toxicity to the host. Disinfectants are usually gross and indiscriminate poisons for cells and need not be further considered here. Antiseptics are usually applied topically and, as they are frequently of such low

toxicity to the cells of the host that they may be used with caution on sensitive tissues, they can often be classed with the chemotherapeutic agents. Bacteria, in contrast with protozoa, are fairly rigid and physically resistant cells but the advent of sulphonamides and penicillin has shown systemic bacterial infections to be vulnerable to successful chemotherapeutic attack. The work of Browning and his collaborators on the acridine antiseptics was a feature of the 1914-1918 war and further vigorous study by Albert and his colleagues (1945) in Sydney has extended our knowledge of this field. The use of the quinine derivative optochin in the chemotherapy of pneumococcal septicaemia in mice (Morgenroth & Levy, 1911), however, was the only known example of the cure of a generalized invasive bacterial infection prior to the introduction by Domagk of the sulphonamides. Modelling their work on Eisenberg's (1913) examination of the antibacterial action of azo-compounds *in vitro* and on the well-known azo-pyridine urinary antiseptics (Hörlein, 1935-6), Mietzsch and Klarer decided to use the azo-benzene molecule as a versatile carrier of substituents, the general method of synthesis being diazotization of an aromatic amine and coupling with another component. Klarer (1943) has given a clear account of the plan of campaign which helps one to understand in some measure the mental reserve which the German workers showed at first to the idea that prontosil (XXVII) was broken down in the body to give sulphanilamide (XXVIII), the substance responsible for the systemic antibacterial activity of the original dye (Tréfouël, Tréfouël, Nitti & Bovet, 1935). Following the lead set in the May and Baker laboratories, the introduction of heterocyclic radicals into the sulphonamide group led in succession to sulphapyridine (XXIX), sulphathiazole and the sulphapyrimidines of increasing efficacy and diminished toxicity, and the maximum degree of efficiency in this group appears to have been reached in the pyrimidine derivatives. The medical uses of the sulphonamides, as well as their limitations, are well known and require no elaboration here, except to remark that their "spectrum" of activity is largely confined to gram-positive aerobic organisms.

Evans, Fuller & Walker (1944, 1945) showed that *p*-methylsulphonylbenzamidinium (V187) (XXXI) and *p*-methylsulphonylbenzylamine (V335) (XXXII) hydrochlorides were similar to marfanil in their biological effects, and, unlike the case with the so-called "sulphonamides", the antibacterial action of these three drugs is not interfered with by *p*-aminobenzoic acid.

### Antibiotics

Although knowledge of microbial antagonisms involving pathogenic organisms goes back to Pasteur, attention was only sharply focused upon this "unassuming commonplace of Nature" by Florey and Chain's successful development of the penicillin produced by Fleming's historic contaminant. The range of activity of penicillin among bacteria and spirochaetes and its lack of toxicity to the host alike distinguish it as the most remarkable chemotherapeutic agent yet discovered. On the chemical side it has proved one of the most tantalizing of natural products ever investigated. Degradation gave two readily recognized fragments,  $\beta$ , $\beta$ -dimethylcysteine and an N-acylated-glycine derivative, but putting the pieces together again to give penicillin has been the alluring but discouraging task of numerous chemists for the past few years both in this country and in the USA. Only traces of antibacterial activity were detected in the products of synthesis and, even if du Vigneaud and his collaborators (1946) have isolated the substance responsible for the small degree of

It was found by Klarer (1941) and Domagk (1942) that interposing a methylene group between the aromatic amino group of sulphanilamide and the benzene ring markedly modified the antibacterial "spectrum" and increased greatly the action of the sulphonamide type of drug on anaerobic organisms of the *Clostridium* group; the resulting drug, marfanil (XXX) hydrochloride, came into wide use in the german army for the prophylactic treatment of wounds. Approaching from an entirely different angle,

activity found and have shown it to be penicillin, the synthesis affords no unequivocal proof of structure. The unorthodox  $\beta$ -lactam structure (XXXIII) for the penicillins is considered to represent their structure more satisfactorily than the oxazolone-thiazolidine formula (XXXIV), R being different in different penicillins.

Chemical engineering has accomplished a remarkably fine feat in the large-scale production of penicillin, coping, as it has had to do, with the necessity for working under sterile conditions, with the labile nature of penicillin, and with the necessity for training personnel in methods hitherto unknown on such a scale. Of other antibiotics, streptomycin is the only one which appears to have established itself as therapeutically of value, although gramicidin and tyrothricin have had a limited application in medicine. The chemical nature of streptomycin has been worked out in American laboratories but, considering the structural formula (XXXV) for streptomycin and that of the penicillins, the prognosis for ultimate preparation synthetically is even less bright than with the penicillins.

Present-day search among the metabolic products of moulds and other micro-organisms for therapeutic agents gives added interest to Samuel Butler's satire on a convert to Sir Kenelm Digby's<sup>2</sup> sympathetic therapy:

Learned he was in med'c'nal lore,  
For by his side a pouch he wore,  
Replete with strange hermetic powder,  
That wounds nine miles point-blank would solder;  
By skilful chymist, with great cost,  
Extracted from a rotten post;

*Hudibras, Part I, Canto II.*

#### *Chemotherapy of Rickettsial and Virus Infections*

We have seen how the more-highly organized protozoal pathogens were the first to come under the control of chemotherapy and then later, descending the scale of biological differentiation, antibacterial chemotherapy became a practical reality. All these organisms, however, lead a free and independent existence and when we descend the scale still further to the rickettsiae of typhus and to the viruses we are dealing with parasites which are poorly endowed with synthetic abilities and which depend upon an intracellular environment for growth and multiplication. The position of the chemotherapy of rickettsial and virus infections has recently been assessed by Andrewes & King (1946) and by Findlay (1948), who have indicated the leads that are available. Andrewes and his colleagues (Andrewes, King, van den Ende & Walker, 1944; Andrewes, King & Walker, 1946) have shown that *p*-sulphonamidobenzamidine (V147) (XXXVI) and *p*-sulphonamidobenzamidoxime (V186) (XXXVII) hydrochlorides have a marked chemotherapeutic action in experimental typhus but human clinical trials, carried out in the wake of battle, were disappointing. A number of American workers have found massive doses of *p*-aminobenzoic acid to be of value in the treatment of some kindred diseases (Rocky Mountain spotted fever, scrub typhus) and dyes of the methylene-blue type have been studied experimentally with success. Penicillin, too, in massive doses has been reported as being active in experimental typhus.

XXXVII

#### *Chemotherapy of Cancer*

In cancer, chemotherapy has a problem which may well prove to be quite insuperable since the cancer cell, after all, is only a modification of the normal somatic cell, and "the conversion of a normal into a malignant cell is possibly brought about by a re-orientation of enzyme constitution of such a kind as would not necessarily involve any great change in gross protein-structure or in immunological specificity" (Haddow, 1947). On the other hand, the difference between sensitive and drug-resistant strains of the same species of bacteria can be similarly defined and we know that the appropriate drug will select and destroy the former strain, leaving the latter relatively unharmed. It has been suggested (Dubos, 1944) that certain gram-negative bacilli in their behaviour toward many types of antiseptics behave much more like animal-tissue cells than do other micro-organisms, and it may be that the chemotherapy of gram-negative infections will eventually suggest methods of approach to the chemotherapy of cancer.

On the practical side, which has been reviewed by Haddow (1947), it has been shown that oestrogens favourably influence cancer of the prostate, and there have been a number of studies of the effect of mitotic poisons on the growth of tumours. The specific cytotoxic effects of the chloroethylamine vesicants, which emerged from war-time biochemical study of these agents, suggested an investigation of their effects on malignant disease in man but it is still too soon to assess the results, and the same applies to the use of urethane in leukaemia.

#### *Theories of Chemotherapy*

Starting from the conception that all biological events are to be interpreted as chemical processes, Ehrlich postulated that "corpora non agunt nisi fixata" and considered that the ideal chemotherapeutic agent should be maximally parasitotropic and minimally organotropic, that is to say, it should have a great affinity for the protoplasm of the parasite and as little affinity as possible for the cells of the infected host. Although he realized that such absolute discrimination would not be possible as is the case in immunology where antibodies are exclusively parasitotropic and "nach Art von Zauberkugeln ihr Ziel selbst aufsuchen", he set himself the ideal of a "therapia sterilisans magna" and sought a drug so powerful that one single treatment should kill all the infecting parasites in a treated host and leave the host unharmed. Ehrlich interpreted his results in terms of his side-chain theory and in terms of receptor groups on the parasites specific for functional groups in the molecules of chemotherapeutic drugs—cellular -SH groups, for example, being the receptors fixing arsenicals to susceptible trypanosomes. In anticipation of modern work, he clearly pictured the possibility of drugs hindering the uptake of essential metabolites and gave a "grobes Beispiel" in a letter to his cousin, Carl Weigert, in 1898 (see Heymann, 1928); his theory of "athrepsy",

<sup>2</sup> Sir Kenelm Digby (1603–1665), an astrochemist, was one of the original Fellows of the Royal Society and a member of what is readily recognized today as the first National Committee for Chemistry.

in fact, accommodates the idea of interference by a drug with a metabolic process. It is obvious, however, that ultimately, any antiseptic action results in the alteration of essential metabolic events.

Chemotherapy has remained essentially an experimental science and such theories as there are, and they are not many, have been evolved to explain observations and not to pave the way for fresh discoveries. This is scarcely surprising when one considers that the biochemistry, and particularly the enzymology, of micro-organisms is still, relatively speaking, in its infancy; the attack on the problem of bacterial nutrition through the analysis of complex empirical media only began to bear fruit little more than a decade ago (see Knight, 1945). Further impetus to theories of chemotherapy came when Woods (1940) showed that a substance isolated from yeast extracts capable of antagonizing the antibacterial action of sulphanilamide had properties recalling those of *p*-aminobenzoic acid, which itself has this anti-sulphanilamide activity. The great similarity in the formulae of sulphanilamide and *p*-aminobenzoic acid led Fildes (1940) to state with greater precision than anyone previously that a drug might interfere with an essential metabolite and so inhibit growth, and that it might do so in one of three ways, of which the most interesting was by competition for an enzyme associated with the essential metabolite. It was postulated that *p*-aminobenzoic acid, whose biological significance first came to light in this extremely indirect manner, was an essential metabolite for certain bacteria and that, in virtue of structural similarity, sulphanilamide, and, of course, sulphonamides generally, displaced it from its enzyme and thus stopped an essential line of metabolic events. Such an inhibition requires an inhibitor so closely related in chemical structure to the essential metabolite that it can fit the same enzyme and yet sufficiently unrelated to be devoid of essential metabolic activity. Further work has shown this simple sulphonamide—*p*-aminobenzoic-acid thesis to be an over-simplification (Henry, 1943, 1944) and, although Fildes suggested that other chemotherapeutic agents might be sought by modelling drugs on known essential metabolites, further intensive work (see Roblin, 1946) has so far failed to produce a single therapeutic agent of practical value, but the qualitative generality of the phenomenon is not in doubt. Although analogues of essential growth-factors frequently inhibit *in vitro* growth of bacteria, they fail to show any chemotherapeutic activity because the metabolites on which they are based are normal constituents of the body-fluids of animals.

The discovery of *p*-aminobenzoic acid in a combined form in compounds of the folic-acid group, such as liver *Lactobacillus casei* factor (pteroylglutamic acid) (XXXVIII), was an event of considerable biochemical interest. There is evidence to show that many bacteria can synthesize folic acid (Sarett, 1947) and in some cases this has been related to the *p*-aminobenzoic acid content of the medium (Mayer, 1943; Mills *et al.* 1944). Recent findings also indicate that sulphonamides inhibit the synthesis of pteric acid from *p*-aminobenzoic acid in the case of enterococci (Lampen & Jones, 1946). If O'Meara, McNally & Nelson (1944, 1947) are correct in their suggestion that reductone,  $\text{CHO.C(OH):CH(OH)}$ , is the strongly-reducing non-sulphydryl substance found in bacterial cultures during the logarithmic phase of growth, it may well be that reductone

provides the 3-carbon unit indicated in bold type in XXXVIII and that sulphonamides interfere with the synthesis of pteric acid from *p*-aminobenzoic acid by competing with the latter for reductone, giving rise to biologically-inert analogues of pteric acid (Forrest & Walker, 1948).

Considerable success has attended the correlation of physicochemical properties of drugs with trends in the biological effects which they produce. For example, the experimental correlation of the acid dissociation constants of sulphonamides with *in vitro* antibacterial activity has shown that maximum activity is found in those drugs which are approximately 50% ionized at the pH of the medium considered (Bell & Roblin, 1942), the shape of the curve obtained on plotting these properties against each other indicating the operation of two factors; a plausible, but incomplete, explanation (Cowles, 1942) is that these drugs are absorbed in the undissociated form and that it is the ion which is active, although diaminodiphenyl sulphone and sulphaguanidine, which have no acidic properties, are embarrassing exceptions. Albert and his colleagues (1945) have shown that, among the aminoacridines, once a minimal degree of basic strength has been attained further increase does not influence antibacterial activity which has already reached a maximum, suggesting a simpler relation between activity and chemical constitution in this series than in the case of the sulphonamides; there is much to indicate that ion-exchange and acid-base neutralization phenomena form the basis of the biological effects of this and certain other groups of antibacterial agents.

The difficulties facing a theoretical approach to chemotherapy as a guide to synthetic operations by the organic chemist are well illustrated by the unfolding of events in the development of paludrine (XXIII). Had one of the suggested working hypotheses been followed unremittently we might, for example, have had a number of extremely powerful antagonists of riboflavin, but we should not have had paludrine. Again, refined speculations in terms of the theory of resonance are of doubtful significance as a guide to the design of new drugs; it is noteworthy that the lower (methyl) homologue of paludrine, to which such considerations apply not one whit less than they do to paludrine itself, is not an antimalarial (Curd & Rose, 1946). Just as in the case of Bayer 205 where the two methyl groups (italicized in IV) are necessary for high biological activity and must occupy the positions shown and no others, so also with the lower homologue of paludrine, the two methyl groups which transform the methyl radical,  $-\text{CH}_3$ , into the isopropyl group,  $-\text{CH}(\text{CH}_3)_2$ , bring out the desired biological activity. One may take an illustration from another branch of applied chemistry where the participants are the cellulose fibre and three related dyestuffs. Congo-red (XXXIX, A and B being hydrogen atoms) has the power of dyeing cotton directly, although the colour is unstable to acids on account of the indicator nature of the dye. Substitution of two methyl groups at the two positions A,

giving benzopurpurin 4B, affords a similar substantive dye with increased stability to acid, but, on the other hand, similar substitution of methyls at the two positions B destroys substantivity altogether, the resulting dye showing no affinity for the cellulose fibre.

In their extensive study of trypanocidal dyes, Nicolle & Mesnil (1906) found that dis-azo dyes of the trypan-blue and trypan-violet type fell clearly into two classes, those that dyed cotton directly and those that did not; trypanocidal dyes fell in the first group and trypanocidal activity, as might be expected, was even more narrowly selective than substantivity. When simple chemical changes in molecules produce fundamental alterations in their behaviour towards the relatively simple and homogeneous cellulose fibre, it seems premature to theorize in terms of the much more complex living cell; in the ultimate analysis, the problem of biological specificity will yield only to experiment and not to argument.

Once the primary observation of biological activity is made on a new type of compound, (and this, of necessity, must be made empirically), the synthetic organic chemist is usually able, in the exercise of his craft, to provide a variety of related types. From the body of circumstantial evidence regarding structure and activity which grows thereby, it is possible with consequent economy of effort to narrow the search for maximum biological activity. In this cursory review of chemotherapy no reference has been made to the participation of the host but it goes without

saying that, whether the chemotherapeutic agent acts directly on the infecting parasites or indirectly through a blockade of some kind, the final act in the recovery process is performed by the body, which may or may not have been an active participant in earlier stages as well.

It is only as our knowledge of the biochemistry of micro-organisms grows that we may expect to reach a fuller understanding of chemotherapeutic processes and that the gaps in chemotherapy may be filled in. If we long ago abandoned the use of Ehrlich's nomenclature with its multiplicity of receptors, we must, at least, look upon it with indulgence, for, as Dale (1923) has pointed out, "Ehrlich's theory will always deserve the credit of having provided a vigorous stimulus to the investigation of problems which, without some kind of working hypothesis, might well have seemed beyond the reach of experimental attack". The intervening years have given us a wide variety of new drugs and control over an ever-increasing number of pathogenic organisms. None of our chemotherapeutic agents, however, is so good as to be incapable of improvement and we must continue to seek for better ones, with enhanced margins of safety and presenting greater convenience in administration. Of penicillin we can entertain no criticism of its remarkable powers as a drug but its production is extravagant in man-power and material, and so the search for new synthetic antibacterial agents will go on, using penicillin as the yard-stick by which the newer drugs are measured. It may be that the chemotherapy of gram-negative infections will be suddenly opened up by a discovery matching the introduction of the sulphonamides, and there are signs that the practical chemotherapy of tuberculosis may not be long delayed. The fruitful collaboration of chemistry and medicine, which has given the physician the power to control with certainty infections which only a decade ago would have proved fatal, gives one a feeling of sober confidence that yet more benefits to humanity will accrue from their continued association.

## SOME MEDICAL CONTRIBUTORS TO CHEMISTRY

TREVOR I. WILLIAMS B.A. B.Sc. D.Phil.

*Deputy Editor, Endeavour*

The debt of medicine to chemistry is well known, and one is constantly reminded of it by accounts of new drugs and anaesthetics, new materials for the construction of medical instruments and equipment, new knowledge of the processes that occur in living cells, and in many other ways. It is, however, much less generally appreciated that chemistry owes a very considerable debt to medicine, for many chemical discoveries of fundamental importance have been made by men whose academic qualification was the M.D. degree and many of whom carried on their chemical investigations while actively practising the profession of medicine. The occasion of the Chemical Society's recent centenary celebrations is an appropriate time to review this subject, for of the seventy-seven original members of the Society no less than fifteen were medical men.

For many centuries science and medicine were so closely interwoven that, especially among the humbler practitioners, it is now often impossible to distinguish one from the other. A slight acquaintance with contemporary knowledge of natural phenomena was frequently sufficient to establish

a reputation as a healer; the term physician did not necessarily connote any specific qualifications and it was only in the higher ranks of the medical profession that any sort of control was enforced. The universities granted medical degrees from a very early stage in their history, and after 1518, when the Royal College of Physicians was founded, physicians practising within seven miles of London had to have the M.D. degree of the universities of Oxford or Cambridge. In England, membership of the Barber-Surgeons' Company or of the Society of Apothecaries became recognized as a definite professional qualification and similar professional organizations were established in other countries. The Barber-Surgeons' Company was formed in London in 1308 and the connexion between barbers and surgeons was not dissolved until 1745, when the College of Surgeons was formed and it was ordained that "no person using any shavery or barbery in London shall occupy any surgery, letting of blood, or other matter, except only drawing of teeth." The Apothecaries were formerly associated with the Grocers but they formed a separate Company in 1617. It will be seen therefore that in England an organized profession of medicine scarcely existed before the fourteenth century, when chemistry was still at the alchemical stage. Not until the sixteenth century did chemistry appear in anything like its modern form.

### *Paracelsus and his Successors*

The first great figure linking chemistry with medicine after the alchemical era was Paracelsus (1493-1541), physician to the city of Basle. Among his many remarkable and sometimes unattractive characteristics was a profound contempt for authority. He used his own authority to order the destruction of existing medical and alchemical textbooks and placed his own views in their place. His greatest contribution to chemistry was his proclamation that the transmutation of base metals into gold must not be

the sole aim of chemical experiments, though he believed that transmutation was a possibility. He taught that for the treatment of disease the pure substances produced by chemical methods were preferable to the empirical and often noxious brews then in common use. Paracelsus introduced many inorganic substances—including compounds of mercury, lead, sulphur, iron, arsenic, and copper—into general medical practice and was thus the founder of medical chemistry, or iatrochemistry as it is called.

Among medical men Paracelsus had several worthy successors to continue his iatrochemical doctrines. Angelo Sala (1575–1640) was physician to the Duke of Mecklenburg and also a chemist of repute. His *Opera medico-chemica* was published in 1647. Among his contributions to chemistry may be mentioned a clear description of ammonia and ammonium chloride and the preparation of nitric acid by the action of sulphuric acid on saltpetre. He was described by Conring as “the first chemist who ceased from trifling.”

Another of the great iatrochemists was Johan van Helmont (1577–1644). Although he came of a noble family, and had estates in Brabant, he chose to give all his property to his sister and to devote himself to serious study. He took his M.D. degree in 1599. Thereafter he turned his attention to almost every branch of the arts and science and made several notable discoveries in chemistry. Perhaps his greatest achievement was his recognition of the nature of gases and his demonstration that there are several different kinds of gases. Earlier chemists had almost entirely ignored the gaseous products of their experiments, no doubt because of the difficulty of handling them with the apparatus at their disposal. Geber, for example, in describing an experiment in which ammonia is evolved, merely states that the nose should be averted from the reaction vessel. Van Helmont prepared carbon dioxide (rediscovered by Black in the eighteenth century as “fixed air”) by the action of acid on marble. He distinguished between gases and vapours. He introduced the use of the temperatures of freezing and boiling of water as fixed thermometric points. More important still, he emphasized the importance of the balance in chemical research. Although he never freed himself entirely from the ideas of the alchemists, and devoted a great deal of time to a search for the universal solvent or alcahest, van Helmont was a shrewd and careful observer and certainly one of the greatest chemists of his day.

#### *Iatrochemists of the XVII Century*

Among others of the early iatrochemists may be mentioned Oswald Croll (1580–1609), who was physician to Prince Christian of Anhalt Bernberg. He was responsible for the introduction into medicine of succinic acid, potassium sulphate, antimoniac acid, calomel, and silver chloride. Guerner Rolfinck (1599–1673) was a physician with very catholic interests in science. He was successively professor of Anatomy, Surgery, Botany, Practical Medicine, and Chemistry at Jena; this is perhaps an unequalled record of academic versatility. According to Stahl, Rolfinck was responsible for having “brought chemistry into shape, deduced its operations from causes conformed into Nature and reason, and laid a foundation on which many subsequently built.” Adrian von Mynsicht (1603–1638) prac-

tised medicine at Helmstadt. He discovered tartaric acid and used antimony sulphide and cream of tartar for the preparation of tartar emetic. François de la Boë, better known as Franciscus Sylvius (1614–1672), a disciple of van Helmont, practised medicine at Amsterdam. At his instigation the first chemical laboratory in Europe was built at Leyden, where he was professor of chemistry. He added considerably to knowledge of salts and their formation. Thomas Willis (1621–1675), the great authority on the anatomy of the nervous system, was also an able chemist. After graduating at Christ Church, Oxford, he practised in London. He investigated the preparation of ether and succinic acid.

John Mayow (1643–1679) was a doctor of laws of Oxford University. He practised medicine in Oxford and in Bath, though he does not seem ever to have gained the M.D. degree. He was in a sense the discoverer of oxygen, “officially” discovered independently by Priestley and Scheele a century later, for he recognized that there is a constituent of air which is concerned with both combustion and respiration.

In the year after van Helmont's death another great iatrochemist was born. He was Nicholas Lémery (1645–1715), who became a doctor of medicine of the University of Caen. Lémery's chemical lectures at his laboratory in the Rue Galande in Paris attracted not only the cream of French society but also numerous students from the whole of Europe. His textbook of chemistry, *Cours de chymie*, published in 1675, was a great success. It passed through thirteen editions in his own lifetime and remained a standard work for more than a century. Lémery was a fine experimentalist and his work did a great deal to clarify contemporary ideas on the preparation and properties of many compounds. He distinguished between organic and inorganic substances. Like van Helmont he appreciated the use of the balance and noted the increase in weight which occurs when lead and certain other substances are calcined. Although he found it difficult to reconcile this with the phlogiston theory he did not understand the real nature of combustion. While in Paris, Lémery is said to have made a handsome living by selling a cosmetic—“le seul Magistere de Bismut”—which was apparently a form of bismuth oxychloride.

#### *Stahl and the Phlogiston Theory*

Georg Stahl (1660–1734) is notable for having developed the phlogiston theory of combustion, postulated originally by Becher. Although the phlogiston theory proved false when subjected to the test of experiment it was in fact a good theory, and its use as a working hypothesis considerably advanced chemical knowledge. Indeed, it was in effect a negative expression of the correct theory of combustion, for the phlogiston theory becomes intelligible if, for the word phlogiston, we substitute “absence of oxygen.” Stahl was a graduate of Jena who became professor of medicine at Jena and later physician to the King of Prussia.

Although Lémery had distinguished between organic and inorganic compounds, Hermann Boerhaave (1668–1738), a Dutch physician, is generally recognized as the founder of organic chemistry. He was professor of medicine and botany, and later professor of chemistry, at the University of Leyden. His *Elementia chemiae* was published in 1724.

The glass and optical industries owe a considerable debt to John Bevis (1693–1771), a London physician who was the first to make glass with borax. He noted that this gave a glass with a high refractive index and thus pointed the way to the achromatic combinations which were developed many years later.

#### *Scottish Pioneers*

Another physician who made great contributions to chemistry, and founded the famous Scottish school of chemistry, was William Cullen (1710–1790). He began his medical career as a ship's surgeon and later became an apothecary's assistant in London. He then practised as a surgeon at Hamilton, Lanarkshire, taking his M.D. degree at Glasgow in 1740. In 1756 he was appointed professor of chemistry at Edinburgh. Among his contributions to chemistry was the discovery that liquids become cold when they evaporate and when certain substances are dissolved in them. Pre-eminent among Cullen's many distinguished pupils was Joseph Black (1728–1799). Black took his M.D. degree in 1754, submitting a chemical thesis, *De humore acido a cibis orto et magnesiae alba*, for examination. Black's work on the relationship between carbon dioxide and the oxides and carbonates of magnesium and calcium considerably clarified contemporary ideas on the nature of chemical combination and also emphasized the importance of quantitative work. He developed Cullen's work on latent heat and his work in this field led to Watt's construction of steam engines. Besides carrying out his extensive chemical investigations, Black found time to look after a large general practice in Glasgow. He was the first to hold the position of Physician to His Majesty in Scotland.

Although the work of the Italian physician Luigi Galvani (1737–1798) was primarily in the physical field, it had nevertheless a considerable influence on the development of physical chemistry. His discoveries formed the background to the electrochemical researches of Michael Faraday, which in turn led on to an understanding of the process of electrolytic dissociation. Hermann von Helmholtz (1821–1894) has a similar claim to consideration. After a short career as an army surgeon he became professor of physiology at Königsberg, Bonn, and Heidelberg successively, but in 1871 his physical researches gained for him an appointment as professor of physics in Berlin. His discoveries—exemplified by his enunciation in 1847 of the conservation of energy in closed systems and the Gibbs-Helmholtz equation relating to chemical reactions—have materially advanced the progress of chemistry. In the same class, too, is Julius Mayer (1814–1878) who, like Cullen, began his career as a ship's surgeon, later taking up a medical appointment in his native town of Heilbronn. He was the first to calculate the mechanical equivalent of heat, a constant of great importance in physical chemistry. Mayer is reputed to have conceived his work on the mechanical equivalent of heat while on a voyage to the East Indies. While in the tropics he had occasion to bleed several members of the crew and he was struck by the unusual redness of their blood, indicating a low consumption of oxygen. From this he was led to consideration of the energy released in the metabolism of food and thence to determination of the mechanical equivalent of heat.

#### *Carl Scheele: The XVIII Century*

The Swedish apothecary Carl Scheele (1742–1786) was responsible for discovering many new chemical substances. The long list of these includes arsenic acid, hydrogen sulphide, arsenic sulphide, chlorine, hydrofluoric acid, and lactic, oxalic, citric, and tartaric acids. He also carried out an extensive investigation of the properties of manganese. He anticipated Priestley in the discovery of oxygen and came close to discovering the nature of combustion.

Work on the study of gases was advanced by Daniel Rutherford (1749–1819), whose thesis for the M.D. degree at Edinburgh defined the difference between carbon dioxide and nitrogen. The acceptance of a chemical subject for the M.D. degree again emphasizes the close connexion that then existed between medicine and chemistry. Rutherford was the first to prepare nitrogen, which he obtained by removing oxygen from air by combustion. Priestley independently obtained nitrogen at about the same time and—a sign of his lifelong adherence to the phlogiston theory—called it “dephlogisticated air.”

Another important figure in the chemical life of the late eighteenth century was Thomas Beddoes (1760–1808). He obtained his M.D. degree at Oxford and afterwards became University Reader in Chemistry. Subsequently he founded the Pneumatic Institute at Clifton, Bristol, primarily with the intention of studying the possible therapeutic effects of inhaling gases. As his assistant he engaged the young Humphry Davy (1778–1829), who at that time was proposing to go to Edinburgh to study medicine. Davy became so absorbed, however, in his chemical work at Bristol—where his discoveries included that of the anaesthetic properties of nitrous oxide—that he eventually abandoned his original intention of qualifying in medicine. Lyon Playfair (1818–1898) was another great chemist who began his career with the intention of qualifying in medicine, an intention which he was forced to give up owing to a breakdown in his health.

A great part of our knowledge of the chemical properties of platinum, and the discovery of a satisfactory method of rendering the metal malleable, is due to William Hyde Wollaston (1766–1828). He graduated as an M.D. at Cambridge and from 1789 to 1800 carried on general practice in various places, finally settling in London. He then abandoned medicine for chemistry and within a few years his mastery of the intractable metal platinum won him a fortune of £30,000. He discovered also the metals rhodium and palladium.

In this catalogue of medical contributors to chemistry, brief mention might perhaps be made of Alexander Marcet (1770–1822), less because of his activities in the field of pure chemistry—where his chief service was in teaching—than because his wife, with his collaboration, did so much to interpret chemistry to the general public. The first of her popular science books, *Conversations in chemistry*, had enormous sales throughout Europe.

Among the greatest chemical figures of the early nineteenth century was Jöns Berzelius (1779–1848), a Swede who graduated in medicine at Uppsala in 1802. From 1807 onwards he taught medicine and pharmacy at Stockholm, adding chemistry to his course in 1815. It is as a chemist that he is remembered. Among the impressive

list of his achievements in chemistry may be recalled his long series of determinations of atomic weights, his experiments in electrolysis, his discovery of selenium, cerium, and thorium, his isolation of columbium and silicon, his introduction of the modern system of chemical symbols, his improvement of analytical methods, and his classification of minerals according to their chemical constitution.

The work of William Prout (1785–1850) on the determination of atomic weights by vapour density measurements, of which he published an anonymous account in 1815, proved of value in clarifying some of the uncertainties about atomic weights which existed in the early nineteenth century. His famous hypothesis—that all atoms are made up of hydrogen atoms and that the atomic weights are therefore very nearly whole numbers—proved incapable of substantiation at the time, but the discovery of isotopes nearly a century later showed that his idea had in fact some substance. Prout was a Gloucestershire man who qualified in medicine at Edinburgh and practised in London.

Although recent study of the contemporary literature tends to diminish the significance which has been attached to his conversion of inorganic ammonium cyanate into organic urea, the chemical researches of Friedrich Wöhler (1800–1882) are well worthy of notice in other respects. His isolation of aluminium in 1827 and of beryllium in 1828 are of particular interest. He also devised a method for manufacturing nickel and carried out important investigations on the phenomenon of isomerism.

#### *Some Irish Chemists*

Among Irish chemists of the nineteenth century Sir Robert Kane (1809–1890) was pre-eminent. At the age of thirty-five he had established a European reputation as a chemist but, unfortunately for chemistry, he was also an able administrator and educationist and as such attracted the attention of Sir Robert Peel, who induced him to take up political work. After qualifying in medicine Kane went to Paris to study pharmacy in 1830. In the following year he was appointed professor of chemistry at Apothecaries' Hall, Dublin. In the same year, at the remarkably early age of twenty-two, he was elected to the Royal Irish Academy. Among his chemical discoveries may be mentioned the synthesis of mesitylene from acetone, the recognition of the ethyl radical, the use of calcium chloride in the purification of methanol, his researches on archil and litmus, and the investigation of mineral manganese arsenide, which was subsequently named Kaneite in his honour. He was a gifted writer and his textbook of chemistry was regarded as the best of its day. In the political field, another book, *The industrial resources of Ireland*, created an equally great impression. He was the founder of the *Dublin Journal of Medical and Chemical Science*, which is still published in the form of a purely

medical journal with the title of *The Irish Journal of Medical Science*.

Another distinguished Irishman of the same period was Thomas Andrews (1813–1885), who took his M.D. degree at Edinburgh in 1835. After practising for a time in Belfast he was elected professor of chemistry in Queen's College, Belfast, in 1849, and held this post for thirty years. Andrews is best known for his important work on the liquefaction of gases and his discovery of the existence of critical temperatures and pressures.

#### *The Chemical Society Founded*

Among the great chemical problems of the early and middle nineteenth century was that of discovering how atoms are linked together to form molecules. For our modern conception of valency much is owed to Friedrich Kekulé, who was for a time a lecturer in chemistry at St. Bartholomew's Hospital, London, but many outstanding problems were clarified by the work of William Odling (1829–1921). Odling qualified in medicine in 1851 and then went to Paris to study chemistry. On his return to England he was engaged in laboratory work and in lecturing on chemistry at Guy's Hospital. In 1868 he succeeded Faraday as Fullerian Professor of Chemistry at the Royal Institution. Later he succeeded Brodie in the Waynflete Chair of Chemistry at Oxford and did not retire from his long life of active chemical work until 1912.

Odling was among the last of the great chemists whose academic qualification was a medical degree. By the middle of the nineteenth century, facilities for the teaching and practice of chemistry and for the exchange of information had become sufficient to meet the rapidly growing interest in the subject without dependence upon the medical profession. The most significant event in this respect was the foundation of the Chemical Society in 1841; for the meetings and publications of the Society proved an excellent medium for the discussion of controversial chemical subjects and the exchange of information. In 1845 the Royal College of Chemistry was founded in London, with W. A. von Hofmann as its first professor. The first university chemical laboratory was opened in Oxford in 1854 and at Cambridge in 1887, though at both Universities chemistry had been taught for some two hundred years previously. A school of chemistry was formed in Manchester in 1851. Adequate training thus became available to all potential chemists, without need to take the medical course.

Medical contributions to chemistry still continue, however, though in a rather different way. Collaboration between physician and chemist, the one venturing some distance into the now vast field of chemical knowledge and the other essaying to master some knowledge of medicine, has proved of great advantage to both, particularly in the study of physiologically-active substances such as antibiotics, vitamins, hormones, and carcinogens.

## TYPHUS AND CHEMOTHERAPY

Prof. A. W. DOWNIE

*University of Liverpool*

This report<sup>1</sup> covers a large part of the work on typhus carried out between 1941 and 1946 at the National Institute for Medical Research, Hampstead, London, and at the Royal Army Medical College Emergency Vaccine Laboratory, Everleigh, Wilts. Publication of many aspects of the work had been withheld for security reasons. The largest part of the report is concerned with observations made during clinical trials of two drugs, in North Africa and Italy. These substances had given highly promising results in laboratory tests recorded in 1944 by Andrewes, King, van den Ende & Walker. The two substances were:

*para*-sulphonamidobenzamidine hydrochloride (V 147)

*para*-sulphonamidobenzamidoxine hydrochloride (V 186)

### Toxicity of V 147 and V 186

The results of toxicity tests in mice, guineapigs, rabbits, rhesus monkeys and man are recorded in the first section by C. H. Andrewes, A. M. Begg & M. van den Ende. The maximum daily dose in g./kg. tolerated *per os* over several days was greater for mice (2) than for rhesus monkeys (0.25) or guineapigs (0.3). A daily dose of 0.13 g./kg. was tolerated by human volunteers without ill-effects.

### Chemotherapeutic Trials

Section II, comprising 118 pages, is a report by the British Army Typhus Research Team on chemotherapeutic trials in typhus fever in man and a report of the 1943–4 Naples typhus epidemic. The team began work in Algiers in July 1943 and although the number of cases available throughout the summer and autumn was small the experience gained was valuable. It was established that the drug V 186 did not produce an obvious clinical effect when given to patients in the second week of the disease. The cases were mostly in Arabs under the age of 40, with a gross mortality from typhus of only 11 per cent. Only one-third of the cases was admitted before the 8th day of the disease. If the diagnosis of typhus seemed likely on clinical and pathological grounds, alternate patients were given V 186. Of the entire group of 65 patients investigated, a final diagnosis of typhus was made in 21, other diagnoses being established in the remainder on the basis of clinical examination and

extensive laboratory investigations. Details of clinical course and laboratory findings are given in respect of the typhus patients. It was felt that V 186 did possibly cause a slow amelioration of the disease but the need for further observations on a large group of patients was obvious. One patient apparently developed kidney damage, either because of the effect of the drug alone, or because of the combined effect of the drug and the lesions of typhus.

### The Naples Typhus Epidemic 1943–4

The Naples outbreak developed in December 1943 and much of the work was transferred to that centre. The chemotherapeutic trial of V 186 was made on new cases admitted to hospital between 2 January and 9 February 1944, the period which included the time of maximal prevalence of typhus in the city (913 cases were reported during January). The American Typhus Commission was very active and co-operative. An analysis of the cases from December 1943–February 1944 showed that the mortality among 1423 cases was 13.9 per cent. There were however 12 deaths among the 50 control cases admitted to hospital and forming part of the trial. A detailed analysis of the clinical course, symptomatology, and physical findings in these cases is presented and tabulated. Similar data are given for 30 patients in the "treated" group: of these, 27 received V 186 and 3, V 147. In the final comparison of the 30 patients in the treated group with the corresponding 30 controls there were 8 in each group classified as severe and, of these, 7 in the treated group died and 5 of the controls. The two groups had been reasonably comparable in duration of illness prior to admission, in age and sex incidence and in symptomatology. In those who recovered there was no difference between the two groups in the duration of fever after admission to hospital. In considering possible toxic effects, vomiting was more frequent in the treated patients and in five a peculiar collapse or shock-like state occurred. There was clinical evidence that V 186 was probably exerting a toxic action on the kidney and in fatal cases severe tubular degeneration of the kidney was found. Penicillin was given to a few of the control cases but did not exert any marked beneficial effect on the course of the disease.

The results of pathological investigations carried out are given in some detail: strains of rickettsiae were isolated from 17 patients by inoculation of blood into guineapigs, and 11 were adapted to mouse lungs. Three attempts were made to isolate rickettsiae from the blood of patients who had been treated with V 186 for 24 hours or more, and all succeeded. Useful data are given on the development of agglutinins for murine and epidemic rickettsia and for *Proteus OX19* and *OX2* in 59 patients. Complement-fixation tests made on some of the sera against freshly prepared rickettsial suspensions gave positive results with epidemic, but negative with murine, antigens. The findings in relation to blood-counts and blood-chemistry are discussed and the morbid anatomy and histology, based on 24 autopsies, is described. As indicated above, tubular degeneration in the kidneys was much more severe in the treated than in the control series.

The reason for the failure of V 186 in the treatment of typhus in man and its success in the mouse is not quite clear and it is suggested that the elucidation of this difference might serve to explain the mode of action of the drug.

<sup>1</sup> [For particulars see Book Reviews.]

### Test for Neutralizing Power of Antirickettsial Sera

In section III, by M. van den Ende & K. C. Mills, experiments on a quantitative test for neutralizing antibodies against typhus rickettsiae are described. The method depends on the determination of the extent of the reduction in the number of focal lesions produced in the lungs of mice inoculated intranasally with rickettsial suspension mixed with progressive dilutions of serum. The inhibitory effect of serum was not noticeably increased by prolonging the contact of serum and rickettsiae for more than half-an-hour before inoculation into mice. The test gave fairly accurate results with sera which were sufficiently potent to reduce the focal-lesion count to 20 per cent., or less, of that in the controls. Many human sera studied, however, were not of this potency. With immune rabbit-sera against epidemic strains, neutralization of murine rickettsiae was poor compared to that against homologous rickettsiae. The reduction in the focal-lesion count was not dependent on the agglutination of rickettsiae. The mouse test gave more satisfactory results than the Giroud test of neutralization by intradermal injection of serum-rickettsiae mixtures into rabbits.

### Comparison of Typhus Vaccines

Section IV, by F. Fulton, M. van den Ende, W. J. Elford & K. C. Mills, is devoted to a study of laboratory methods for comparing the potency of typhus vaccines. The methods of preparation of four murine vaccines, two from yolk-sacs (A and B) and two from mouse lungs (C and D) of approximately equal rickettsial content, are described. Two of the vaccines were highly purified, one (A) from the yolk-sac by Craigie's ether method, the other (B) from mouse lung by the kieselguhr method which, in its improved form, is described in detail in the succeeding section. Photomicrographs of representative fields of the four vaccine-suspensions are reproduced on plate X. The vaccines were standardized after the number of rickettsiae present had been estimated by the microscopical examination of stained films. The potency of the vaccines was compared by: (a) active immunization of guineapigs by one intraperitoneal injection of vaccine; the animals were tested 37 days later by intraperitoneal injection of a yolk-sac suspension of living rickettsiae; (b) protection of mice by a single dose of vaccine against the toxic effect of a certainly fatal dose of rickettsiae injected intravenously; and (c) by the production of antibodies in vaccinated rabbits and guineapigs. The rabbits received three doses of vaccine intravenously at four-day intervals. The guineapigs were those used in method (a) and were bled for serum before the challenge dose of living rickettsiae was injected. The antibodies studied in sera of immunized rabbits and guineapigs were: rickettsial agglutinins, agglutinins for *Proteus OX19*, complement fixing antibodies, "antitoxins", and neutralizing antibodies. The titres of antibodies were lower in the guineapig sera than in the rabbit sera. *Proteus OX19* agglutinins were present in the rabbit sera only in small amounts—highest titre 1/40—and were not tested in the guineapig sera. By these methods, no significant difference in the antigenic potency of the four vaccines was detected and it is concluded that potency depends on the number of rickettsiae present and is independent of the soluble antigen. The power of a vaccine to protect mice

against the toxicity of rickettsiae injected intravenously affords the most convenient and reliable test for vaccine potency.

### Antigenic Structure of Typhus Rickettsiae

In section V (29 pages), a detailed serological study of the antigenic structure of typhus rickettsiae by F. Fulton & A. M. Begg is presented. The Wilmington murine strain and a Cairo epidemic strain (isolated in 1942) were used in most of the work. Immune rabbit- and guineapig-sera were obtained from animals after a single intraperitoneal infecting-dose of rickettsiae from yolk-sacs or mouse lungs. For some of the later experiments rabbits were immunized by intravenous injection of *Proteus OX19* suspension or by repeated intravenous injections of various rickettsial antigens. Agglutination tests and the complement-fixation reaction were used throughout. Purified suspensions for agglutination tests and for absorption of sera were prepared from rat- (murine strain) or mouse-lungs. Antigens for complement fixation were prepared in the same way, although yolk-sac antigens were also used in the experiments on soluble antigen. The working hypothesis adopted by the authors was based on the propositions: (i) that the antibodies formed in response to one antigen are not entirely uniform but vary in specificity to some degree, and (ii) that the heating of some antigens to 100°C. creates a new antigenic specificity.

From the results of their carefully-planned experiments with unabsorbed and absorbed sera, the authors reach the following conclusions: the surface antigen of the murine strain of typhus rickettsiae is similar to, but not identical with, the surface antigen of the epidemic strain; the murine rickettsial surface-antigen gives rise to a heterogeneous group of antibodies, some of which can react with the surface antigen of the epidemic strains; similarly the epidemic surface-antigen gives rise to antibodies, some of which react with the murine surface-antigen.

Boiling a rickettsial suspension so alters the surface antigen that it acquires a new serological specificity. Such degraded antigens have lost their strain-specificity. Rabbit and guineapig rickettsial antisera contain an antibody which reacts with boiled rickettsiae but this antibody is entirely distinct from the antibody which reacts with the undegraded rickettsiae. The *OX19* antibody of rabbit rickettsial antisera is entirely distinct from the antibodies to the undegraded surface-antigen of the rickettsiae, but it is a fraction of the group of antibodies which reacts with the boiled rickettsiae. Shaking a rickettsial suspension with ethyl ether provokes the release into the surrounding fluid of a soluble antigen which behaves as if it were a fragment of the surface antigen, though there is evidence that it is partially degraded.

### Case Reports and Drugs Tested

In appendix A (50 pages) are set out summarized reports of 13 representative cases which illustrate the respective features of severe, moderate and mild typhus treated with or without chemotherapy. An account of the postmortem findings and histology is given with the reports of the six fatal cases. Some of the histological lesions found in typhus cases are illustrated by excellent photomicrographs on plates II-IX. A second appendix gives a list of the

## FACTOR ANALYSIS IN PSYCHOLOGICAL MEDICINE

Sir CYRIL BURT

*Professor of Psychology  
University College, London*

The application of statistical methods to problems of psychiatry is of quite recent origin. Yet it promises to throw a new and revealing light on many unsolved problems.

The idea of disentangling contributory causes by means of a statistical analysis is due to Galton. The fundamental technique is the calculation of a coefficient of correlation, which was intended to assess the relative importance of a common cause or factor by measuring the amount of agreement between its effects: it was used, for example, to measure the influence of inheritance in a physical characteristic, such as stature. Later, Galton was led to study the concomitant variation of a number of characteristics considered as a group. Thus, in discussing Bertillon's scheme of physical measurements for the identification of criminals, he pointed out that what was really needed was a set of traits showing as little intercorrelation as possible. Pearson carried this argument to its logical conclusion; and showed how the variations of a large number of intercorrelated characteristics might be described in terms of a small number of uncorrelated factors. Thus, in physical measurements, we find a "general factor" for size, accounting for the fact that growth in all directions is more or less proportionate, and a special or "bipolar factor" for body-build, accounting for the familiar classification of individual physique into the well-known leptomorphic and pachymorphic types (Kretschmer's asthenic and pyknic types).

The first psychologists to use correlational methods for the study of mental capacities were Galton's own pupil, McKen Cattell, and Cattell's younger colleague Wissler. They assumed that, with mental traits as with physical, both general and special factors would be found. Spearman, however, made the startling suggestion that all the intercorrelations between mental characteristics could be attributed to one general factor only. Although his view is no longer accepted, the eager controversies that

it aroused led to a vast number of factorial studies, mainly concerned with tests of intellectual abilities. Owing partly to the pressing needs of educational organization, and partly to the accessibility of children for mental testing, the greater part of this early pioneer work was carried out by educational psychologists, schoolteachers, and school medical officers, working in London schools. From a practical standpoint, the most important outcome was the demonstration of an innate, general, intellectual factor popularly known as "intelligence", and the development of standardized tests for the diagnosis of mental deficiency and for educational and vocational guidance generally.

The problems referred to the school psychologist, however, included not only cases of intellectual deficiency and special disabilities, but also cases of emotional or moral disorders—delinquency, psychoneurosis, and so-called moral deficiency. Here the problems of classification and causation were still more bewildering. Accordingly, as early as 1915, it was suggested that the factorial technique might be fruitfully applied to the investigation of the emotional aspects of human personality. Almost at once, a general factor of emotionality was clearly established, together with bipolar factors reminiscent of the old traditional temperaments. The former, it was suggested, indicated the element of truth contained in McDougall's notion of a "common fund of emotional energy" and Jung's later doctrine of *libido*. The latter provided a confirmation of Binet's distinction between "objective" and "subjective" types of personality, and the analogous distinctions between "extraverts" and "introverts" (or "cyclothymes" and "schizothymes") as suggested by Jung and Kretschmer. By 1923, factor analysis had provided a convenient working scheme for the study of what was called "personality",<sup>1</sup> which has been used freely in child-guidance clinics and elsewhere; and, what was even more important, the method made it possible to assess, with some approach to scientific accuracy, the relative importance of different contributory causes and of different diagnostic symptoms in various subnormal conditions.

During the last twenty years these statistical devices have been taken up with great enthusiasm in the USA under the lead of Kelly, Holzinger and Thurstone. The chief results are brought together by Dr. Raymond Cattell in his recent book, *The description and measurement of personality*.<sup>2</sup> The change in viewpoint will be seen at once on comparing this work with that of Gordon Allport on personality.<sup>3</sup> Allport's masterly review followed the

## CHEMOTHERAPY IN TYPHUS

*Continued from page 374*

numerous drugs tested in the laboratory for activity against typhus by Andrewes, King, van den Ende & Walker (1944).

Although the chemotherapeutic trials against typhus fever were not successful under the conditions in which they were carried out, the detailed clinical, biochemical, serological and pathological investigations made during the trials and reported in this monograph constitute a valuable record of louse-borne typhus as seen in North Africa and Naples in 1943 and 1944.

The laboratory studies on the immunology of typhus fever, made at the National Institute for Medical Research and at the Royal Army Medical College Emergency Vaccine Laboratory, are an important contribution to knowledge in this field.

## REFERENCE

Andrewes, C. H., King, H., van den Ende, M. & Walker, J. (1944) *Lancet*, 1, 777

impressionistic studies of Jung, Freud, and Stern, and appeared before the wave of statistical researches on human personality had fully reached America. In his own survey, Dr. Cattell enumerates about thirty different factors, all apparently well established in the sense that they have been found by at least three independent observers. Many of these, however, seem to be different names, or allied forms, of much the same thing; and he believes it possible to reduce the entire list to about twelve fundamental components. To a large extent these correspond with the factors already discovered in Britain. They include general ability (or intelligence), certain special intellectual abilities, general emotionality, and a number of temperamental factors. Most of them have definite implications for psychiatric work; and some seem primarily concerned with clinical or abnormal states. Of these the most important and the most conspicuous is that making for a cyclothymic or schizothymic temperament; others make for melancholia, hysteria, neurasthenia, paranoia, anxiety, and their respective opposites.

Dr. Cattell's list of factors, as he himself emphasizes, is provisional only. But it is evident that, if this procedure is applied rigorously and systematically to further trustworthy data, it will do much to solve the puzzling problems of the classification of nervous and mental disorders. The accounts that are now being issued of the results obtained by psychologists and psychiatrists, both in Britain and in the USA, suggest that in two or three points his conclusions will need revision. He has evidently overrated the validity of behaviour-ratings and personality-tests as compared with personal questionnaires; he tends to describe normal characteristics in terms of psychiatric concepts rather than vice versa; and he is apt to force as many factors as possible into bipolar form. These defects, however, are defects rather of the material available at the time of his investigation than of Dr. Cattell's own standpoint.

A recent book, *The dimensions of personality*\* by Dr.

Eysenck, carries the results still further. It records the results of more than three dozen separate researches carried out on several thousand normal and neurotic subjects. Most of the work was done at Mill Hill Emergency Hospital, and the majority of the patients were men and women referred from the Armed Forces. An important feature of the investigations has been the close collaboration between medically-qualified psychiatrists and a group of non-medical psychologists using such specialized techniques as standardized tests and factorial analysis.

The investigators "started from the position that measurement in the field of personality is impossible until the dimensions along which such measurement can take place are known." The field of survey has not been limited entirely to normal or abnormal traits of temperament, but covers bodily physique and constitution, intellectual ability and efficiency, aesthetic appreciation and expression, and problems of hypnosis and suggestibility. A separate chapter is devoted to each of these main topics. Much the same factors or dimensions are discovered as before; and the same "hierarchical view of the structure of personality" is in the main confirmed. In particular, the analysis of the data obtained from neurotic cases has fully corroborated two main factors—which (subject to certain reservations) are labelled "neuroticism" and "extraversion-introversion" (or "hysteria-dysthymia").

Dr. Eysenck and his colleagues have discussed, in the light of their evidence, the value of physical types, physiological symptoms, and personality-tests for the diagnosis of psychoneurotic and psychotic disorders, and for the discrimination of the main subclasses. They frankly admit that their conclusions are tentative and sometimes even negative. That is almost inevitable in view of the material available. But their results demonstrate two points beyond all question: first, the value of co-operative research on common problems approached simultaneously from the standpoints of the psychiatrist and the psychologist respectively, and second, the value of testing tentative hypotheses and current views by an adequate statistical technique.

## SOME MEDICAL CONFERENCES

Among the medical conferences being held this summer we have received notice of the following:

*In London.* International Congress on Mental Health, Central Hall, Westminster; from August 11-21, 1948, under the presidency of Dr. J. R. Rees, C.B.E. The Congress will be in three main parts: (1) Child Psychiatry—Theme: Personality development with special reference to aggression (August 11-14, morning sessions); (2) Medical Psychotherapy—Theme: Guilt (August 11-14, afternoon sessions); (3) Mental Hygiene—Theme: Mental Health and World Citizenship (August 16-21). All enquiries should be addressed to The Congress Organizer, International Congress on Mental Health, 19 Manchester Street, London, W.1.

Under the auspices of the Commission Internationale Permanente pour la Médecine du Travail, the Ninth International Congress on Industrial Medicine—the first for 10 years—is being held at the Caxton Hall, London, S.W.1, from 13 to 17 September, 1948. The Congress will be in six sections dealing with Social Aspects, Environment, Nursing, Clinical, Practice, and Special Subjects. Visits to Rehabilitation Centres, Clinics, Hospitals, etc., during Congress week and the week following are being arranged. The address of the Organizing Secretary is Room 501, Garden Court Wing, BMA House, Tavistock Square, London, W.C.1.

\* \* \*

*At Salzburg,* the Austrian Medical Conference will be held on the 6, 7 and 8 September, 1948. The two main subjects of the Conference will be Blood Transfusion and Hypertension. Enquiries to the Sekretariat der oesterreichischen Aerztetagung, Salzburg, Landeskrankenhaus.

\* \* \*

*In Budapest,* in connexion with the centenary celebrations of the Hungarian War of Liberty, 1848, the Hungarian Medical Trade Union is arranging a Medical Week from 4 to 12 September, 1948. Detailed programmes will be sent, on request to the General Secretary, the Hungarian Medical Trade Union, Budapest V, Nádor Utca 32.

\* \* \*

*Les Entretiens de Bichat* 1948. In Paris the second annual series of informal discussions is to take place from the 10-17 October at the Hôpital Bichat. There will be two series of 100 discussions: (i) on surgery and various specialities (oto-rhinolaryngology, electro-radiology, gynaecology and obstetrics, ophthalmology, stomatology), from the 10-13 October, under the direction of Professor D. Petit-Dutaillis; (ii) on large questions of general modern medicine, from the 14-17 October, under Professors Guy Laroche and L. Justin Besançon.

The discussions are arranged in four series, each of 2 days, and are to be carried out with the help of 100 doctors from Paris hospitals, who are abreast of the latest clinical and therapeutic advances. Outlines of each subject will be supplied beforehand, and then discussed informally. Abstracts of all the introductory talks are to be published in September before the discussions by the Expansion Scientifique Française, 23 rue du Cherche-Midi, Paris.

Last year's colloquia, which were most successful, were attended by 842 french and foreign practitioners. Enrolments for 1948 can be sent to the Hôpital Bichat (Paris 18<sup>e</sup>).

## FRENCH WAR-TIME RESEARCHES

It is difficult enough for those who did not actually experience nazi occupation to imagine how ordinary life was carried on,

under material and moral conditions which defy description. It is still more difficult to visualize the continuance of scientific research under such conditions. It was the resulting attitude of incredulity which struck Professor Pasteur Vallery-Radot on a post-war visit to America and gave him the idea of publishing a collection of articles which would be representative of the extensive and varied medical researches actually carried out in France during the war. This project, in which he enlisted the services of Professor Jean Hamhurger, of the Paris Faculty of Medicine, has resulted in an impressive volume entitled *Recherches médicales en France pendant la guerre (1939-1945)*, and containing 30 articles. Many of these had already been published, in journals or as part of a book, but several were written specially for this collection. The variety of subjects is wide, ranging from the purely clinical, as in the articles by Debré, Marie, Seringue & Mande, "Remarks on a neuro-oedema syndrome" (p. 7) and Gutmann, "Initial signs of gastric cancer" (p. 53), to details of chemical and bacteriological research, as in the articles by Nitti, Tabone & Mousset on "The antisliphonamide activity of peptone" (p. 245) and Lépine on "Studies on the determination, by means of ultracentrifugation, of the size of bacteriophages" (p. 39). The authors mentioned are but a few of the eminent authorities included among the contributors. Other examples are: Leriche, "Remarks based on 800 lumbar gangliectomies"; Lacassagne & Danyss, "Three notes on mammary cancer in mice" and two articles by Vallery-Radot and others on "Clinical and biological discussions of polycystic kidneys" and "Effect of sulphonamide therapy on the kidney".

The reader cannot help being impressed by this wide range of subjects and the wealth of detailed and careful investigation that has been carried out. The criticism that there is no evidence, in this haphazard collection of individual observations, of any planned research into particular fields, while true as an isolated statement, is surely one which ignores the conditions, described in Vallery-Radot's preface, under which the work was done, and which played such an important role in the genesis of the book. The expressed object of this volume is to show the outside world that, in spite of indifference, and even active opposition, from above, french scientific workers still "carried on" under the german occupation. In these circumstances, planned research would hardly have been possible, and the book aims merely at presenting representative samples of the work accomplished. A more valid argument would seem to be that the editors might well have arranged their material more systematically, grouping the articles by subject, even though the work described was actually done independently, instead of in an apparently arbitrary order. This would have been a great improvement from all points of view; it would have answered even more satisfactorily those sceptics who believed french scientific investigation to be at a standstill during the war, by showing at once how much had been done in each field; it would have facilitated reference; and lastly, it would have created a more orderly impression in an otherwise excellently produced book.

The physical composition of the book is of a high standard: paper and type are good; the half-tone illustrations (radiographs, etc.) leave something to be desired, but the tables and graphs are neat in appearance and, on the whole, clear. An attractive and useful feature is the brief summary at the beginning of each article, printed in italics and enclosed in a "box". Full bibliographies are appended to most articles, but it is a pity that no consistent style for references appears to have been used.

It would seem appropriate to say a special word on the subject of indexes. There is a list of contents in chronological (and therefore haphazard) order, but no index to this book. This exemplifies an all too frequent omission in french works, often, as in this case, lowering the generally high standard of production. In addition to a subject index, an alphabetical list of authors would be useful here.

In spite of these few criticisms, however, it seems to us, in the first place, an interesting and useful idea to publish a book of this kind and, in the second place, that the editors' aims have been, for the most part, fulfilled. The book cannot fail to impress its readers and will be a lasting tribute to the achievements of France in medical research under the occupation.

## ANTI-TUBERCULOSIS MEASURES IN SPAIN

Five books<sup>1</sup> issued during 1945, 1946 and 1947 by the *Patronato Nacional Antituberculoso*, which deal with tuberculosis control in Spain, have reached us. Two of these books are entitled *La lucha antituberculosa en España*, one being a book of 366 pages, published in 1945 and giving a detailed account of the activities of the *Patronato Nacional Antituberculoso* (PNA), its organization, administration and future plans. It includes statistical information on the results of investigations by PNA into the incidence of tuberculosis in Spain, and gives particulars of the services which have been set up to combat this disease. The second and smaller book was published in 1946 and gives a summary of the progress made by the PNA since its foundation in 1936 in the provision of services for tubercular patients. Many new sanatoria have been established and the number of beds available for tubercular patients has risen from 2,500 in 1936 to 11,000 in 1946. One of the preventive measures adopted by the PNA has been the establishment of settlements for children with a family history of tuberculosis. Both these books are illustrated with numerous photographs and tables.

The other three publications of the PNA deal with special aspects of the antituberculosis campaign. *La tuberculosis pulmonar inadvertida*, 1946, by Dr. Jose Zapatero stresses the importance of early x-ray diagnosis and gives details of radiological investigations carried out among various groups of the population such as soldiers, miners and students. Dr. Zapatero emphasizes the need for increased sanatorium accommodation. *Estudio de las contralateralizaciones, especialmente precoces, en los procesos pulmonares tuberculosos de apariencia radiológica unilateral*, 1946, by Dr. F. Tello-Valdivieso contains clinical histories of a number of his patients at the central antituberculosis dispensary in Zaragoza, and gives an account of their treatment and progress. The book is illustrated by numerous plates and includes a bibliography. *Estudios sobre el pulmón colapsado*, by Dr. Jose Abelló Pascual, 1947, reviews briefly the history of the treatment of pulmonary tuberculosis previous to the introduction of pneumothorax, and continues with sections on the macroscopic and histopathological anatomy of the collapsed lung, the mechanism of collapse and collapse therapy. Brief clinical histories are given in an appendix. The book is illustrated and contains a bibliography.

The PNA acknowledges that it has profited greatly from the experience of similar organizations in other countries. Its founders visited antituberculosis centres abroad, studied their organization and were grateful for the advice of their directors. Their hope is now that the work and publications of the PNA will be of use to colleagues in other countries and they invite visitors to come and see what has been accomplished in Spain and the work in progress there in the campaign against tuberculosis. When present plans are completed, 20,000 beds will be available for tubercular patients and Spain will have one tuberculosis dispensary for every 100,000 citizens.

## THIRD INTERAMERICAN CONGRESS OF SURGERY

We have received three volumes<sup>1</sup> containing the texts of papers and addresses read at the Third Interamerican Congress of Surgery held in Montevideo in October 1946. The congress was organized by the *Asociación de congresos interamericanos de cirugía*, whose function it is to arrange surgical congresses at two-yearly intervals, to which affiliated societies may send delegates. Usually, three special subjects are chosen for the attention of the congress, and on this occasion these were: Complications and sequelae of surgery of the biliary tracts, Surgical treatment of cancer of the oesophagus, and The treatment of fractures of the pelvis. The texts of papers on these and on other subjects are included in these volumes. Bibliographies, indexes and a list of the statutes of the Association, make up a very complete and interesting account of the congress.

## THREE IMPORTANT NEW BRITISH JOURNALS

Was it in a flash of prophetic wisdom that the Preacher cried out that of the making of many books there is no end? But how else should it be? As the field of knowledge and enquiry grows ever wider it becomes inevitable that it must be divided and subdivided; and natural that each subdivision, as it amasses new facts, should demand a vehicle for the publication and dissemination of its findings and techniques. Three subdivisions which in the last year have found it necessary to seek their own medium of expression are social medicine, nutrition, and plastic surgery. Of these the last-named is by far the youngest and most highly specialized, while the first to some extent includes the broader aspects of the second.

*British Journal of Social Medicine*. In turning first to social medicine, it may not be inappropriate to recall that just a hundred years ago, in a revolutionary Europe, the conception of medicine as a social science was taking shape. In Britain, Chadwick's classic Report on the sanitary condition of the labouring population had been published and created no small stir; in 1848 the first Public Health Act was passed. Now at last social medicine has its own journal; no. 1, vol. 1 appeared in January, 1947, and the first volume of four parts has been successfully completed. It is one of the group of attractively-produced journals published by the British Medical Association, and is edited by Professors F. A. E. Crew and Lancelot Hogben with the assistance of a distinguished editorial committee.

The editors have defined the scope of social medicine in the following terms:

As understood by those who are responsible for this Journal, social medicine is that branch of science which is concerned with: (a) biological needs, interactions, disabilities, and potentialities of human beings living in social aggregates; (b) numerical, structural, and functional changes of human populations in their biological and medical aspects. . . . Social medicine takes within its province the study of all environmental agencies, living and non-living, relevant to health and efficiency, also fertility and population genetics, norms and ranges of variation with respect to individual differences and, finally, investigations directed to the assessment of a regimen of positive health.

It will be seen then that the field is, in one respect, a wide one, making possible the inclusion of a great diversity of papers, but these will be confined for the most part to "work done", and it is expressly stated that the journal "is not meant to provide a platform for those who wish to present their views concerning the place of social medicine in the organizational set-up of medicine as a whole." The full contents of this interesting new journal are given in the Guide to the Journals in the present and previous numbers of this Bulletin and may be seen to range from "Dietaries in maternity hospitals" to "Studies on age and wastage in industrial populations", or "School medical inspections, their value and limitations."

The size of the journal is convenient and the format very pleasing; one small but useful point which we noted with pleasure was that at the top of each article is given its correct bibliographical reference.

*British Journal of Nutrition*. While, as has been seen, some of the wider problems of nutrition fall within the sphere of social medicine, others come in the purely medical or biochemical fields. But in practice, articles on one or another aspect of nutrition have been scattered in a wide variety of journals. In the attempt to cover most of the field the editors of *Nutrition Abstracts and Reviews*, for example, are obliged to scrutinize several hundreds of periodicals from the world literature of which not more than perhaps half a dozen are devoted solely or mainly to nutrition.

Nutrition in Britain as a science *per se*, then, has long felt the need for having its own journal and now, with the appearance of the *British Journal of Nutrition*, this gap has, in part at least, been filled. The first number of vol. 1 appeared in September, 1947, and the volume has recently been completed by the appearance of a double number (2-3). It is the intention, however, that future volumes should consist of four quarterly parts. The journal is published by the Cambridge University Press for the Nutrition Society of Great Britain, and is edited by an editorial board, composed of names all well known in the nutrition world, under the chairmanship of Dr. S. K. Kon of the National Institute for Research in Dairying.

The first part of each number consists of original articles. These have dealt with e.g.: vitamin studies, the composition and nutritive value of certain foodstuffs, the food requirements of various domestic animals, haemoglobin levels in pregnant

women, and metabolic studies in starvation and severe under-nutrition. The second part of the number contains the Proceedings of the Nutrition Society (both of the English and Scottish groups), formerly published separately but now incorporated in the journal. The subjects of the three conferences of the Society reported in this volume are of more than sectional interest, dealing as they do with "Education in nutrition"; the "Preservation, colouring and flavouring of foods"; and "British needs and resources of calories, protein and calcium." In addition short abstracts of papers communicated to ordinary scientific meetings of the Society are given. The journal is well produced and printed and we look forward to future issues with interest.

*British Journal of Plastic Surgery.* It is little more than a year since the formation of the British Association of Plastic Surgeons; now they have celebrated their first birthday by the production of a very handsome first number of the *British Journal of Plastic Surgery*, the official organ of the Association. Though a comparatively young branch of surgery, plastic surgery received a powerful impetus through the demands made on it by the crippling and disfiguring injuries sustained in two world wars and it has made rapid and daring progress, sometimes with strikingly dramatic results. But it is not only to the injuries of war that plastic surgery has brought relief and rehabilitation; the art has been applied to the often equally disabling consequences of industrial accident, of burns, and of congenital defects.

In this first number the opening article, by Sir Harold Gillies and Dr. R. J. Harrison, treats of a rare condition, congenital absence of the penis, and of the details of operative reconstruction—phalloplasty. The next article, of wider appeal, by Sir Archibald McIndoe, deals with deformities of the male urethra. In the third article, Mr. Rainsford Mowlem describes an operation involving the construction of a "lymphatic bridge" in the treatment of lymphoedema. Two articles, by Mr. J. B. Cuthbert and Mr. F. T. Moore, respectively, deal with the pollicization of the index finger after loss of the thumb; while in the last article Mr. M. C. Oldfield describes an operation for repair in the congenital condition of syndactyly.

The journal, which will not be confined to the field of a specialty but will include contributions from all allied branches of surgery and dentistry, has been launched with the blessings of the President of the Royal College of Surgeons of England and of a past President of the Royal College of Surgeons of Edinburgh. Professor Paterson Ross contributes a very interesting note on postgraduate surgical training, in which he discusses the relationship of the specialist surgeon to the general surgeon, and of the specialists to each other, and shows how they may derive mutual benefit.

The editor, Mr. A. B. Wallace of the Department of Surgery, Edinburgh University, and the publishers, Messrs. E. & S. Livingstone, are to be congratulated on this very fine production.

To these three new journals we venture to offer a welcome and to wish them a long and fruitful life. For surely Ecclesiastes was altogether too gloomy in thinking that much wisdom is much grief and he that increaseth knowledge increaseth sorrow.

1217

## BULLETIN OF THE WORLD HEALTH ORGANIZATION

We have received the first number of this long-awaited periodical, which replaces not only the *Bulletin of the Health Organisation* of the League of Nations but also the *Bulletin mensuel de l'Office international d'Hygiène publique*. For the present it is being published in only two editions, English and French, but it is hoped later to publish it in several other languages. It will contain communications submitted by representatives of the Member States during the sessions of the Assembly and of the Executive Council, official reports from the expert committees, and original articles by experts and specialists attached to WHO. As pointed out in the editorial, however, the new health organization has a wider scope than its forerunners and this may be expected to influence the final character of the *Bulletin*. This first number, in the nature of its contents as well as in format and general lay-out, closely resembles the old League of Nations publication. Nearly half the space is taken up by an article on tuberculosis in Greece illustrated by well-reproduced photographs. For the rest, there are reports from two expert committees, on biological standardization and on malaria; a series of notes on

the immunity reaction after vaccination and on post-vaccinal encephalitis (two of the urgent questions referred to the Interim Commission of the new organization by the Office international d'Hygiène publique); and articles on rodent infestation in ships, on relapsing fever, and on the anti-malaria campaign in Greece in 1946. The periodical is well printed on reasonably good-quality paper and shows evidence of careful editing. Bibliographical references, for instance, are uniform in style for the most part, the abbreviations of the titles of periodicals being appropriately enough, in accordance with the code drawn up by the International Institute of Intellectual Co-operation in 1930, a style now familiar to English readers through its use in the *World List of Scientific Periodicals* and in a large number of scientific periodicals published in this country and in America. There are however a few cases as, e.g. on p. 197, where authorities are quoted in the text without any reference being given, a practice that causes much annoyance and loss of time to anyone wishing to consult the originals. We wish the new *Bulletin* well and heartily share the editor's hope that it may become a medium for forging strong intellectual links between its readers in all countries.

Cyril C. Barnard

1218

## SURGICAL ANNALS

The *Annals of the Royal College of Surgeons of England*, which began publication in July 1947, has now completed its first volume. As explained by Sir Alfred Webb-Johnson, the President, in a Foreword, the new journal is designed to serve as a medium for the publication of lectures delivered at the College and will also include items of historical interest, accounts of recent events, and a diary of forthcoming functions, lectures and practical classes. The decision of the College to make the world conversant with recent advances in surgery and with the corporation's multifarious activities by the publication of its own journal will be widely welcomed. The journal is issued monthly and is edited by Sir Cecil Wakeley; format and general production are excellent. In the past the medical corporations of Great Britain have been responsible for the publication of many books, catalogues and reports, but, unlike the Colleges of Physicians and Surgeons of America, they have never issued their own journals over any considerable period. We cannot remember any British journal comparable in scope and purpose to the *Annals*, but honourable mention must be made of the *Medical Transactions* published by the Royal College of Physicians, in six volumes, between 1768 and 1820.

The first volume of the new journal contains lectures by Major-General Philip Mitchiner on gangrene and on surgery in two wars; by A. C. Lendrum on painful tumours of the skin; by R. W. Nevin on the surgical aspects of intestinal amoebiasis; by H. S. Souttar on recent advances in the treatment of carcinoma of the oesophagus; by V. E. Negus on injuries and cicatricial stenosis of the larynx; by Sir Lionel Whitby on blood transfusion and intravenous therapy; by Rainsford Mowlem on the replacement of skin losses in traumatic injuries; by E. Sprawson on foods and feeding as they affect teeth and their environment; by W. K. Livingston on physiological responses to wounding; by R. J. V. Pulvertaft on post-operative pulmonary embolism; by T. Cecil Gray on the use of d-tubocurarine chloride in anaesthesia; by M. Forrester-Brown on operative procedures in poliomyelitis; by J. R. Learmonth on the problems of portal hypertension; and by Sir Cecil Wakeley on vogue and fashion in abdominal surgery. There are contributions by three of the most distinguished American surgeons of the present day: Dr. Frank Lahey's Cecil Joll Lecture on hyperthyroidism; Dr. Arthur W. Allen's Moynihan Lecture on duodenal ulcer; and Dr. Evarts Graham's Lister Oration on some aspects of bronchiogenic carcinoma. Several articles and notes deal with the Royal College itself. Professor Willis writes on the Museum of Pathology and Mr. Le Fanu on the vicissitudes of the College Library during the war. On the historical side we note the Vicary Lectures of Sir Arthur MacNalty on the Renaissance and its influence on English medicine, surgery and public health and of Dr. E. Ashworth Underwood on naval medicine in the reigns of Elizabeth and James the First. Sir Arthur Keith breaks new ground in writing on John Hunter as a psychologist and Sir Heneage Ogilvie writes on a hundred years of gastric surgery. Interesting notes on

Hunter's bust in Leicester Square and on "Robin Adair," the romantic eighteenth century surgeon, appear over the initials of the distinguished President of the College.

W. J. B.

1219

## MEDICAL BOOKMAN AND HISTORIAN

*The Medical Bookman and Historian*, a monthly journal now in its second volume, commenced publication in January 1947, as the *Medical Bookman*. By November it had established itself and, under the direction of a distinguished editorial board, was renamed *The Medical Bookman and Historian*. In this form it represents the first english journal devoted to the cultural and historical aspects of medicine.

1220

## EXCERPTA MEDICA

This is a dutch enterprise with its central administration in Amsterdam, and a chief Editorial Board of three, headed by Prof. M. W. Woerdeman to direct the general medical side of the project. Vol. 1, no. 1 of most sections appeared in 1947 and a few are still awaited in 1948.

*Excerpta Medica* aims at providing a comprehensive abstracting service of world medical literature to replace such reliable journals as the *Zentralblätter* and *Berichte* of Julius Springer Verlag, Berlin, that have totally disappeared during the war years. Its service is claimed to be more comprehensive and wide-spread than any provided by earlier journals, and it is proposed to include abstracts of every article published in every available medical journal in the world. They will all appear in the english language and will be arranged in separate sectional journals as follows: Section I Anatomy, Anthropology, Embryology and Histology; Section II Physiology, Biochemistry and Pharmacology; Section III Endocrinology; Section IV Public Health and Social and Industrial Medicine; Section V General Pathology, Pathological Anatomy and Bacteriology; Section VI Internal Medicine; Section VII Pediatrics; Section VIII Neurology and Psychiatry; Section IX Surgery; Section X Obstetrics and Gynaecology; Section XI Oto-, Rhino-, Laryngology; Section XII Ophthalmology; Section XIII Dermatology and Venereology; Section XIV Radiology; Section XV Tuberculosis.

1221

## A NEW SPANISH ABSTRACTING AND INFORMATION SERVICE

*Boletín Noticiario Internacional Médico* (Madrid) is a new weekly journal designed to provide medical men in Spain with abstracts in Spanish of important articles originally published in other countries, especially the USA, Great Britain, France, Switzerland, Sweden, Italy and the Argentine. The editors undertake to obtain for readers a reprint of any complete article in its original language or in Spanish, and it is hoped to form a library containing works by specialists in Spain and elsewhere. It is hoped also to have a translation service, in connexion with the library, which would specialize in medical translations. Films from the USA will be shown from time to time. The first number (vol. 1, no. 1, February 1947) of this journal contains abstracts from various british and american journals.

1222

## A NEW MICROFILM SERVICE

In the first number of *Unesco Monitor* (August 1947, published from Unesco House, Paris), which contains mainly information about educational and cultural activities, the following note is inserted:—

A new microfilm service to spread knowledge on bacteriology and allied sciences has been put into operation by the Pasteur Institute of France.

The service is free of charge to all who require literature on research methods in bacteriology. Upon request, the Pasteur Institute will supply microfilms of any article in the reviews and journals available.

It is expected that the service will greatly assist the dissemination of information on the latest materials and techniques in that field of science.

1223

## AN ASSOCIATION OF MEDICAL LIBRARIANS

The need for an association of medical librarians which would correspond, for instance, to the Medical Library Association of America, has long been felt in Great Britain, the formation of such a body having actually been suggested by Sir William Osler, as long ago as 1909, at the annual meeting of the British Medical Association. This need has now been met by the formation of a medical subsection of the Library Association, under the chairmanship of Mr. C. C. Barnard, Librarian of the London School of Hygiene and Tropical Medicine; the inaugural meeting was held on 4 October 1947 and attended by librarians from medical institutions in all parts of the country. Membership is confined to members of the Library Association, but medical men and others interested will always be welcomed as guests at meetings.

The principal projects designed to increase the efficiency of the medical library service consist of: the compilation of a union list of medical periodicals, which will serve as a guide to the sets held in british libraries; inter-library loans; and an exchange system for duplicate and unwanted books and periodicals, which will help librarians to complete imperfect sets. A monthly bulletin is also being issued, both as a medium for the exchange of news and views and as a link between members separated by distance and unable to attend all the meetings.

In addition to these activities, regular meetings will be held, at which talks by medical men and others will be given, and papers on technical and bibliographical questions will be read and discussed; visits to places of professional interest will also be made.

The first meeting of this kind was held at the National Institute for Medical Research, Hampstead, and was well attended, both by librarians and the medical profession. The subsection was welcomed to the Institute by the Director, Dr. C. R. Harington, and the meeting was then addressed by Dr. George Popják, of the Biophysics Department of the Institute, who gave a very interesting talk on Elementary Biophysics; finally, Miss Wigmore, the librarian, outlined the history of the library and members and guests were shown its many interesting features. The success of this meeting, which owed much to the kind co-operation of the National Institute for Medical Research, augurs well for the future.

The secretary of the subsection, Mr. W. J. Bishop, of the Wellcome Historical Medical Library, 183 Euston Road, London, N.W.1, will gladly answer enquiries from librarians and members of the medical profession.

H. M. C.  
A. H.-S.

1224

## PUBLICATIONS AND REPORTS

From Argentina comes an interesting report of work done there for sufferers from leprosy and for their dependants. This report, entitled *Memoria correspondiente al ejercicio vencido el 30 de abril de 1944*, is published by the Patronato de Leprosos of Argentina and contains a comprehensive account of the work done during that year by the various committees and societies affiliated to the Patronato. Reports from the regional leper centres throughout the country are included, as well as a list of donations received, and an index. The report is illustrated with photographs of colonies under the control of the Patronato de Leprosos, and of the preventive colonies where children of leper parents are cared for.

The Instituto de Perfeccionamiento Médico-Quirúrgico, Buenos Aires, has sent us a copy of *Conferencias—1945*. This book contains the text of a number of lectures delivered during that year. The subjects dealt with include total gastrectomy in cancer

of the stomach (Professor I. Goni Moreno), conservative treatment for gangrene of the extremities (L. Feldman), observations on the clinical, radiological and surgical interpretation of disorders of dental origin of interest to the surgeon (R. A. Vivone), and a general review of homoeopathic treatment as applicable to surgical cases (A. N. Mazetti). The book is illustrated with photographs, tables and diagrams and an index is included.

\* \* \*

The Institut de Recherches sur le Cancer de Lille was founded in 1936 by a franco-american effort of co-operation, and is the only establishment in France devoted exclusively to research, as opposed to the clinical problems of diagnosis and treatment, on the subject of cancer.

We have received a report (*Institut de recherches sur le cancer de Lille*, Cité Hospitalière, Lille, 1946) issued by this institution, which describes its foundation, objects, general organization and methods of work in some detail. The work carried out at the Institute since its opening in 1939 is summarized in two sections: the annual reports of the director, and a bibliography of papers published by members of the staff. A section of photographs of the building and details of the administrative council and technical staff are also given.

1225

# JOURNALS NEWLY RECEIVED

*Notes on journals received for the first time, usually in exchange with the British Medical Bulletin*

*Jornada Médica* (Buenos Aires) is a new journal, of which vol. 1, no. 1 appeared in June 1947. It is published monthly and is designed principally for medical practitioners whose time for reading is limited but who wish to keep abreast of new developments in medicine. Both theoretical and clinical aspects of medicine will receive attention and the editors hope their journal will help to disseminate knowledge and thereby prove beneficial to patients. The first number contains four original articles, dealing with the clinical aspect and treatment of amoebiasis by Dr. Silvio Parodi, the construction and grafting of a finger by Dr. Francisco E. Arespacochaga, influenza and seasonal colds by Drs. Hernán Gonzalez and Carlos Floriani, and acute intestinal obstruction by Dr. Armando F. Giordano. A special section is devoted to translated extracts from the *Archives of Internal Medicine* and further sections contain abstracts from other journals and bibliographical comments.

The *Boletín Mensual* of the *Instituto Nacional de Previsión Social* (Buenos Aires) is a monthly journal which began publication in 1946. In the editorial of vol. 1, no. 1 (October 1946), the first number we received, the hope is expressed that this new journal will play a useful part in the investigation of social problems in Argentina, in finding a solution for them, and in awakening the public conscience to their existence. The Instituto Nacional carries out investigations and research into social questions and in this number of its journal publishes some of the results of its enquiries. The first article is contributed by members of the legal department of the Institute and examines the legal position of illegitimate children in Argentina. The text of resolutions and decrees made by the Institute is also included, with statistics relating to its finances.

The *Revista Médica de Rosario*, of which year 37, nos. 5 and 6, May and June 1947 have been received, is the official organ of the *Círculo Médico de Rosario*, Argentina. The May number contains four original articles and book-review and abstract sections. The June number contains six original articles, book-review and abstract sections and notes of meetings of medical societies in Rosario.

\* \* \*

From Australia come the *Clinical Reports of the Adelaide Children's Hospital*, vol. 1, no. 1, May 1947, the first attempt to publish details of the work of this hospital, at which, in 1947, 5,557 children were treated as in-patients, and 65,072 as out-patients. The *Clinical Reports* are to appear from time to time

and the Editorial Committee plans to publish the second number in November 1947. While the Committee realizes that papers in the journal must generally be based on continued medical practice, it hopes that they may contribute to the sum total of knowledge and to the wellbeing of the child. There are articles in this number on The treatment of influenzal meningitis, Leukaemia in children, and Acute osteomyelitis treated by penicillin. *Clinical Reports* should be a useful addition to the small number of paediatric journals in the english language.

\* \* \*

The first number of vol. 2 (January 1947) of *Klinische Medizin* was received from Vienna. This journal, sub-titled "austrian journal for scientific and clinical medicine", appears on the 1 and 15 of each month and is published by Urban & Schwarzenberg. The price per quarter is S.18, per single number S.4. All editorial communications should be directed to Prof. Dr. L. Arzt, Wien IX, Alserstrasse 4.

Among the original articles in this number are communications on the mechanism of aerophagy, infectious diseases in Austria in 1946, diagnosis and therapy of typhus, and the radiography of joints. A section of abstracts of articles in other journals is also included—in this number all from the *British Medical Journal*.

\* \* \*

Copies of two publications issued by the University of Minas Gerais have reached us. The first of these is the *Anais da Faculdade de Medicina* of the University (year 4, vol. 2, 1945), which consist of the texts of four lectures delivered by members of the Faculty of Medicine and six original articles. These lectures and articles deal with diverse subjects, which include a study of changes in the blood serum in 100 cases of leprosy (O. Versiani Caldeira & E. A. de Cerqueira), clinical notes of a patient suffering from cobra-bite (O. de Magalhães), and a study of the prophylactic and therapeutic properties of sulphadiazine, sulphapyridine and sulphanimide, especially in malaria (S. Americano Freire, C. Cristoff & W. Lobato Paraense).

The second of the publications is the *Anuario da Faculdade de Medicina* (year 5, vol. 3, 1946). This journal is composed of reprints of ten articles contributed to brazilian journals by members of the Faculty.

*Anais da Faculdade de Medicina do Recife*. This journal is the official organ of the faculty of medicine of Recife, Brazil, and no. 10-11 for years 10 and 11 (1943-1944), published in 1946, has been received. This number contains three articles, the first being a contribution to the study of yaws (J. Lôbo). The second article, on Manson's schistosomiasis, is the text of a lecture delivered at a medical congress in Recife by Dr. H. Menezes, and the third article deals with cutaneous amoebiasis (S. Campos). This number also contains a book-review section and statistics issued by the department of morbid anatomy.

*Arquivos de Clínica* (Rio de Janeiro) is now in its third year of publication and no. 3 of vol. 3 for September 1946 has been received. This number contains the second part of an article, the first part of which appeared in the previous number, on clinical haematology (Michel Jamra), an account of inflammatory lesions of granulomatous type seen in human visceral leishmaniasis (Luigi Boglioli) and a contribution on the treatment of liver disease (S. A. Portis). An account of some meetings of the Faculty of Medicine of Rio de Janeiro and news and abstract sections complete the contents.

*Arquivos da Faculdade Nacional de Medicina* is the official organ of the faculty of medicine of Brazil University and is published in Rio de Janeiro. It was founded in 1946, the first number being dated July 1946. The journal publishes original articles, and this number contains nine contributions which include the following: sclerosing bone sarcoma of the femur with clinical notes (Castro Araujo), the metabolism of iodine (A. Couceiro & E. De Robertis, and oligophrenia accompanied by multiple intercranial calcifications (J. L. Lopes).

*Brasil Médico-Cirúrgico* (Rio de Janeiro) year 8, no. 5-6, October-December 1946, contains four original articles dealing respectively with pulmonary embolism, by Drs. Egidio S. Mazzei, Taylor Gorostiaga & Elyescr Magalhães; sigmoiditis with

perforation, by Drs. Adolfo Dujovich & S. Form; gastroenterology, by Dr. Manoel F. Garcia; and the historical foundations for specialization in the field of internal medicine, by Dr. Pedro Nava. The section of notes for practitioners, which is a regular feature of this journal, gives in this number clinical details of some cases of diphtheria in children. In conclusion there is a list of journals received, and a news section.

Also from Brazil comes *Ginecologia* (Recife), which appears every two months, and which started publication in 1946. We have received no. 4 (August 1946), which contains three original articles, including a contribution from Dr. James Young dealing with the development of obstetrical studies in Great Britain, and some notes on medical folklore among primitive peoples by Dr. Ferreyra dos Santos. The journal also gives detailed accounts of the opening ceremonies of the new Universities of Bahia and Recife.

*Neuronio* is a quarterly bibliographical journal published in São Paulo, of which we have received vol. 8, no. 1, for the first quarter of 1947. This journal publishes in Portuguese abstracts from latin-american journals, and also from time to time original articles. The present number contains 26 pages chiefly devoted to abstracts arranged under subject headings, and there is a short news-section.

*Revista de Higiene e Saúde Pública* (Rio de Janeiro) is the official organ of the Sociedade Brasileira de Higiene. The number for April-June 1947 inaugurated a new series of the journal, then in its fifth year of publication. The editorial expresses the hope that the journal will play a useful part in the work for the betterment of world health. The number opens with a biographical note on Dr. Fred Lowe Soper, a member of the Sociedade Brasileira de Higiene, recently appointed director of the Pan-American Health Division in Washington. Other features are articles on the importance and geographical distribution of some of the mosquitoes found in Brazil, and on the diseases prevalent in the province of Alagoas. News and abstract-sections are also included.

We have received for the first time a copy of *Revista Médica Municipal* (Rio de Janeiro) a periodical which is published quarterly and is the official organ of the Public Health authorities. This issue, no. 1 of vol. 8, contains five original articles, which include a contribution from Dr. Joaquim de Brito on the treatment of stomach wounds from various causes, a review by Dr. Leão de Aquino of some outstanding events in the history of the Hospital Sanitário São Sebastião, with the text of addresses and articles published at various times in connexion with these events, and an article by Dr. Herminio Linhares on meningo-encephalitis in rats caused by a filtrable virus. Sections containing news, book reviews, abstracts from foreign journals, lists of journals received and their contents complete the number.

\* \* \*

*S'vremenna Pediatriya* (Contemporary Pediatrics) (Sofia), year 1, vol. 1, no. 7-8, 1947 is largely devoted to full abstracts of papers in world medical journals, on paediatrics and related subjects. The first article is an abbreviated version in Bulgarian of a paper on scabies by Gordon & Unsworth (*Brit. med. Bull.* 1945, 3, 209, BMB 776).

\* \* \*

*Archivos de la Sociedad de Cirujanos de Hospital* (Santiago de Chile) is a quarterly journal for surgeons of which we have recently received no. 2 of vol. 16, which appeared in June 1946. This number is divided into four sections, the first of which contains fifteen original articles. Among these are articles dealing with emergency treatment for gastro-duodenal ulcer by Dr. Marcial Baeza, melorheostosis by Dr. Orlando Poblete Nuñez, anal fissure by Dr. A. Schwartz, and acute torsion of the great omentum by Dr. Adolfo Dujovich. Most of the articles contain clinical histories of patients treated by the authors, with details of the response to the treatment given. The second section gives particulars of lectures and conferences of special interest to readers of the *Archivos*, and the remaining sections contain abstracts, notices and news.

\* \* \*

*Repertorio de Medicina y Cirugía* (Bogotá) was founded in 1909 to assist in the dissemination of medical knowledge in Colombia. No. 5 of vol. 2, July 1947, contains five original articles (on rabies, cancer of the gravid uterus, two surgical conditions, and menstrual epilepsy) and the first of a series of lectures on anaesthesia. Summaries in Spanish, and in some cases a bibliography, are given at the end of each article.

\* \* \*

Among the journals from Czechoslovakia reaching us for the first time is the *Bratislavské Lekárske Listy*, the journal of the Slovak University Medical Faculty and of the Slovak Medical Association, vol. 26, no. 9, September 1946. An effort is made to obviate the barrier raised by the use of the slovak language by giving lengthy summaries in Russian, English, French and German. In the english summaries, the translation is very literal, the spelling is sometimes phonetic, and there are many printer's errors; however, through these obscurities the general meaning of the articles appears, and the purpose of the summaries is achieved.

There are original articles on: complications of wounds of the cranium, Raynaud's disease, myocardial infarction in youth, surgical therapy and roentgenotherapy of struma, treatment of lip cancer.

We have also received vol. 47, no. 8 (1947) of *Ceskoslovenska Stomatologie*. Although it is an attractively produced journal on good paper, printed in clear type, it does not look for readers outside Czechoslovakia, as no summaries are given in other languages to guide the western european reader to its contents. What is more useful from the czech standpoint is the inclusion of comprehensive abstracts from world literature on dental subjects.

\* \* \*

*Anales* (Quito) is the official organ of the Universidad Central de Ecuador, which was founded in 1651. No. 322 of vol. 73 (January-December 1945) contains some very interesting features. There are sections dealing with medicine, history, education and literature. The medical section contains the text of a lecture on cancerology delivered by Dr. César Ricardo Descalzi at the Hospital Civil de San Juan de Dios, and a detailed study of three cases of erythroblastosis by Professor César Jacome. Professor Gonzalo Rubio Orbe contributes an interesting study of the Ecuador Indians, and also included in this number are some chapters of a work on the history of Ecuador in ancient and modern times which are being published in serial form, by Dr. C. Reginald Enock, F.R.G.S. The section of University news gives a summary of the chief events of the academic year 1945-46.

\* \* \*

*Le Progrès Médical* (Paris) is a well-known weekly of high standing, now provisionally appearing twice monthly, under the editorship of Professor Maurice Loeper and Dr. Maurice Genty. Apart from original articles and reports of lectures, it contains brief accounts of society meetings, abstracts of articles from both french and foreign journals, a section on the history of medicine, and a notes-and-news section. The subjects of the original articles in the number for 24 June 1947 (year 75, no. 12) are: Neptal and hypertonic subtosan (M. Perrault & P. Rousseau); Incomplete physiological section of the spinal cord (J.-A. Chavany); An attempt to find a biochemical test of the activity of massive rectal doses of vitamin D<sub>2</sub> (J. Desbordes & G. Feuillet). A report of a lecture by J. Boureau on Analgesia and anaesthesia in obstetrics is also given, and a further interesting feature is an article by G. Barraud, in the historical section, on roman medicine.

*Le Journal de Physique et le Radium* (Paris), of which we have received the number for February 1947 (series 8, vol. 8, no. 2), is published by the Société française de Physique. The main part of the journal is devoted to original articles, of obviously high scientific standard, on subjects connected with physics and radium; the majority of these are preceded by brief summaries. There is also a section of abstracts of articles from french and foreign chemical and physical journals, arranged under subject-headings; and finally a section containing reports of meetings of the Société française de Physique. The two last-named sections each have their own pagination followed by appropriate symbols. The typographical format is clear and of a standard

worthy of the subject-matter of the journal, while it is noteworthy that importance is obviously given to matters of style in such items as bibliographies and headings of abstracts.

Another french journal which we have received is *Monde et Médecine* (Paris), edited by J.-R. Frugier, with the assistance of a distinguished editorial committee, and published by Les Editions Universelles. Its sub-title describes it as an international review of the medical sciences, and the two numbers we have seen (no. 10, October–November 1946, and no. 11, December 1946–January 1947) consist entirely of original articles, mostly clinical, though some are of a more general nature, such as a report on the commemoration of the fiftieth anniversary of Pasteur's death, and an article on the effects of the atomic explosion at Hiroshima.

*La Revue Générale de Médecine et de Chirurgie de l'Union Française* (Algiers), now appearing once a month instead of three times a month as in pre-war days, is issued by the Société d'Expansion Médicale et Pharmaceutique. It publishes review articles, sometimes original, sometimes reproduced from french or foreign journals, on subjects of particular interest to the general practitioner in the french colonies. It also includes a bibliography section. The number for March 1947 (year 24, no. 494) consists of 14 articles, all reproduced from french journals, and the bibliography section, containing reviews of some half-dozen books.

After six years of interruption, due to enemy occupation and postwar difficulties, we welcome the re-appearance from Athens of the *Archives of Hygiene* (third period, 5th year, January–March 1947, nos. 1–3). The journal is an impressive royal quarto production, printed in clear type on beautifully crisp paper, and well illustrated with large charts. Conditions of health in Greece during the war, the enemy occupation and postwar years are reviewed by the Director-General of Hygiene; there is a synopsis of epidemics in Europe, an account of the achievements of UNRRA as an international health organization, and of the creation of the World Health Organization to which Greece looks with other nations for aid, in the rehabilitation of the people's health. "On the occasion of the re-edition of the *Archives of Hygiene*" the editor states the journal's aim is "to give an historic and real picture" of the task of rehabilitation of the greek people and to put greek scientists in contact with the new methods and inventions of the war years so that they may be properly introduced into Greece.

One of the most attractive of the new journals to reach us from Europe is the monthly international journal of paediatrics, *Paediatrica Danubiana*, published in Budapest. Articles are published in English, Hungarian, Russian, French or German, together with summaries in all five languages. The journal is well printed and illustrated, and its pocket-size (20 × 15 cm.) convenient to handle.

In the foreword to the first number, the editor-in-chief, Professor P. Kiss, states the aim of the journal to be the endeavour "to broadcast the results of the research of doctors throughout the world who are striving to improve the health and happiness of children." The names of a large number (40 in vol. 2, no. 6) of editors from all over the world appear on the title-page.

The first number, which appeared in January, 1947, contained articles on renal diabetes accompanied by rickets, by R. Debré, Paris; on primary atelectasis and birth trauma, by A. Eckstein, Ankara; on a method for the radiographical diagnosis of ear diseases in infants, by C. Gefferth, Budapest; on the effect of penicillin after antrotomy in infants and children, by E. György, Budapest. In each number is a short section containing abstracts of articles on paediatrics, from journals of various countries; for example, in the first number, from the *British Medical Journal* and from the *British Medical Bulletin*.

Manuscripts and correspondence should be sent to the Editor, Bókay János-utca 53, Budapest VIII, Hungary. The annual subscription is 22 hungarian florins, or \$9.

We have received vol. 1, no. 1 of the *Indian Journal of Malarology*, March 1947. Since papers published in this excellent journal may be contributed from sources other than the Malaria Institute, this more general title has been chosen to

replace the earlier *Journal of the Malaria Institute of India*. The latter had in 1938 succeeded the *Records of the Malaria Survey of India*. In vol. 1, no. 1 of the *Journal of the Malaria Institute of India*, the Director, Major-General Sir Gordon Covell, gave the history of the activities of the Malaria Survey of India from 1927–37. In the first number of its successor, he gives an account of the valuable work of the Malaria Institute of India from 1938–47.

Most of the contributions to this number are on malaria control, the de-weeding of tanks and ponds, the uses of insecticides with special reference to DDT; there is one clinical paper on certain aspects of paludrine.

Most interesting and useful bibliographical features are (a) the list of contents, arranged by volume and number, of the *Records of the Malaria Survey of India* and the *Journal of the Malaria Institute of India*, and (b) a classified list of publications from the beginning of the Malaria Survey of India in 1927, which forms Appendix III to the history of the Malaria Institute of India.

\* \* \*

*Rassegna di Neuropsichiatria* is the official organ of the Ospedale Psichiatrico Consortile di Nocera Inferiore, Salerno. This hospital was founded in 1883 and two years later began publication of a journal called *Il Manicomio* which was later replaced by *Archivio Generale di Neurologia, Psichiatria e Psicoanalisi*. The latter ceased publication during the war years and the *Rassegna di Neuropsichiatria* now takes its place. We have received for review vol. 1, nos. 1–2 of this new journal. The first article is by Professor Carmelo Ventra and gives an account of the Ospedale Psichiatrico during the years 1940–46. The area surrounding the hospital was heavily bombed and it suffered much damage, while problems of feeding and hygiene within the hospital became very difficult. The mortality rate began to rise in 1941, reaching its maximum in 1944, but since then has steadily declined. This number contains six further original articles, including one by Dr. L. Bini, of the Clinica delle Malattie Nervose e Mentali of Rome University, on the use of shock therapy in some unusual cases of psychosis. Clinical histories of cases treated are given. Dr. Domenico Rossi contributes an article on the psychopathology of chorea minor, and Dr. Giannetto Cerquetelli gives an account of his results in the treatment of multiple sclerosis with histamine. The journal also contains book review and news sections.

*Annali d'Igiene* is a journal published at two-monthly intervals under the auspices of the Istituto d'Igiene of Rome University. The first number to reach us is no. 1, of the 57th year, January–February 1947, which contains five main contributions. These include articles on exanthematous typhus during the italian expeditionary force's campaign in Russia (A. Spezzaferrì), some enzymatic properties of penicillin (F. Mulé) and an investigation into the question of whether an ultravirus may cause whooping cough (M. Carpano). This number also contains abstract and news sections.

Another journal from Rome is the *Giornale di Medicina Militare*, published under the auspices of the Direzione Generale di Sanità Militare, and now in its 94th year of publication. No. 5 for September–October 1947 contains articles on physical work and emotion in the pathogenesis of "soldier's heart" (G. Donati), peritonitis following perforation of the small intestine in typhoid (E. Zaffiro), and an account of gangrenous lung abscess with empyema cured by penicillin (P. Scaduto & A. Cimino). Also included are abstract and news sections.

Published in Naples, *Archivio di Tisiologia* appears at two-monthly intervals, and no. 4 of vol. 2, 1947 contains approximately 172 pages. The journal is divided into two distinct sections with separate paginations, the first being devoted to topics of general medical interest, and the second containing main articles on tuberculosis and allied subjects. The former section in this number contains accounts of three congresses held in Britain on tuberculosis and public health. The first of these articles, which is accompanied by an english translation, is an account of the Edinburgh Congress of 16–19 July 1947, to which the author was invited. He records his impressions of the Congress, and also of his subsequent visits to sanatoria and health centres in Britain. British clinical methods and operative techniques are compared with italian procedure.

*Tumori* (Milan), the official organ of the Istituto Nazionale per lo Studio e la Cura dei Tumori, is published at two-monthly intervals and is now in its 34th year. We have received no. 1-2 of vol. 21, series 2 1947, which contains eight original contributions. The first article of this number reviews the activities of the Institute since its foundation in 1928. Mention is made of much-appreciated gifts of books to the library from the USA, Britain and France, of the inauguration of a committee whose members visit the sick poor in their homes, and of the work of the various departments of the Institute. There are seven other original articles and an abstract section.

\* \* \*

*Sugestiones* (Mexico) contains some interesting features. In the number for June 1947 (year 11, no. 142) is a transcription of some pages from the book by Professor Alejandro A. Bogomolets on the prolongation of life. This particular passage discusses the question of what might be considered a normal life-span and gives a number of instances of continued human activity to an advanced age. An article on leprosy in Monterrey is contributed by Dr. A. Peyri who was formerly in charge of the leper island of Providencia. He gives details of treatments given to some of his patients and of the results obtained. Dr. J. López Durán writes on sex hormones, and there are also articles on the treatment of anaemia by Dr. J. G. Isabet, the use of vitamin D in the treatment of some skin diseases by Dr. José F. Brun, complete arrhythmia and mitral stenosis by Dr. Jorge Meneses Hoyos, a study by Dr. Pavón Serrelangue of a case of partial control of the autonomic nervous system, the diagnosis and treatment of deep wounds of the praecordium by Dr. Joaquín Maass Patiño, and the problem of malnutrition by Dr. Ramón Osorio y Carvajal. The journal also contains a section of bibliographical notes, a list of new books, and an article by Dr. Fausto Zerón Medina, in the *Artistas Médicos* section, on the doctor-poet Gabriel Guerrero Ibarra.

Also from Mexico comes *Química y Farmacia* (vol. 12, no. 109, Jan. 1947), the official organ of the Colegio de Química de México, and the number under review is the first to reach us. The editorial of this number emphasizes the need for co-operation between all peoples in order to further human progress. The contents include an article on the determination of the carotene, fat and protein content in maize; Part VI of a study of alchemy, medicine, pharmacy and pharmacopoeias from the 16th to the 20th centuries; biographical notes on Leopoldo Río de la Loza, a chemist, and Andrés del Río, a mineralogist; and a study of popular nutrition in Mexico, which stresses the advisability of increasing the cultivation of maize.

\* \* \*

The *Boletín del Ateneo Médico de Lima* publishes original articles on medical subjects with clinical histories of interesting cases, and also has a section containing abstracts from journals published in Spanish. The first three numbers of this journal to reach us were: vol. 2, nos. 1, 2, 3 (January-June 1947).

Another peruvian journal is the *Boletín de la Sociedad Química del Perú* (Lima, vol. 12, no. 4, December 1947). This number contains articles and the first instalment of the memoirs of Fernando C. Fuchs Carrera. Señor Fuchs Carrera has been connected with mining in Peru for fifty years and his memoirs are to be continued in serial form in subsequent numbers. Notes of the Sociedad Química and a list of publications received are also included.

*La Protección Materno-infantil en los Últimos Cinco Años*, Lima, is a report for the years 1940-1944, published by the peruvian Ministry of Health on its work on behalf of mothers and children. During the period reviewed the number of prenatal clinics and dispensaries for mothers and children was increased, and home-nursing facilities improved. It is noted that during these years there has been an encouraging decrease in infant mortality. The report gives an account of the present organization of the maternity and child-welfare services in Peru, and there is an appendix summarizing the principal resolutions and decrees in operation for the protection of mothers and children.

\* \* \*

The first number of the fortnightly journal, *Nowiny Lekarskie Dwutygodnik Społeczno-Naukowy*, to reach us from Poland is vol. 54, no. 21, 1947. The two main contributions are: a paper by Tomaszewski on vitamin A in health and disease, reviewing the subject and giving the results of his own research, as published in various polish journals and in the *Edinburgh Medical Journal*; and an account of two cases of polyradiculoneuritis by Jasiński. There are also items of polish medical news and a reproduction of the British Council Monthly Lists of new british medical publications for July and August 1947.

\* \* \*

*Revista de Psicología General y Aplicada* (Madrid) has been founded in order to form a link between all those who are interested in psychological problems, and as a medium for the exchange of information. The journal is published quarterly and each number will contain, in addition to original articles of psychological interest, information about new publications of interest to specialists in psychology. It has also been arranged to publish in each number a translation of an article from the *Psychological Review*, the organ of the American Psychological Association. From time to time an entire number will be devoted to some current psychological problem.

The first number (vol. 1, no. 1, 1946) of this journal contains 316 pages and six original articles, and also sections containing notes on laboratory tests and apparatus, bibliographical notes, reviews and news.

*Archivos de Enfermedades del Corazón y Vasos* (Barcelona) was founded in 1922 and is the organ of the Instituto de Medicina Práctica. The February-March number of vol. 30 (1947) contains three original articles, the first being a study of the arterial pulse and its dichrotic waves by Professor M. Bañuelos, of the Faculty of Medicine, Valladolid. Dr. Domingo de G. Durán Arrom contributes an article on certain diseases, such as rheumatism, arterial hypertension and cardiovascular syphilis, which damage the circulatory system. Dr. Arrom also contributes a section of clinical notes on cardiological practice. This number contains in addition a section of aphorisms, a therapeutic index, a news section containing abstracts from other journals and a bibliographical section.

*Galicia-clínica* (Corunna), is a monthly journal which publishes articles, news and book reviews of medical interest. No. 1, year 19, January 1947, contains 68 pages, and includes articles dealing with the treatment of burns (E. Sáenz Figueiras), the treatment of osteomyelitis (A. J. Echeverri), haemocultures and agglutination reactions and the interpretation of results (F. Beato), the extraction of foreign bodies from the oesophagus (Ortega). The news and book-review section gives information about appointments, events and new publications in Spain of medical interest.

*Odontoiatria* (Madrid) is described as an ibero-american journal devoted to the study of the mouth, its disorders and treatment. No. 23 of vol. 2, November 1945, the first to be received by us, contains four articles which include contributions on vitamin C in relation to gingivitis (J. S. Restarck & M. Pijoan), dental affections commonly found in air-crews (S. Forteza), and the psychological study of the patient (B. Martínez-Gil de Bretón). In addition, this number contains an editorial, book reviews printed on perforated pages to facilitate their easy removal for filing, and an abstract section.

\* \* \*

During 1947, we received vol. 21, nos. 1-3 of the *Quarterly Bulletin of Northwestern University Medical School* (Chicago). This beautifully-produced journal is printed in clear type on fine paper, and it has many good charts and illustrations. It is divided into two main sections, scientific and general; in addition there are an editorial, news of the Medical School, and a list of recent publications of the Medical School Faculty. Among the more interesting of the scientific papers are a series on work at high altitude, by Friedemann, Ivy and collaborators; and recent advances in hepatic and biliary disease, by Snell, with references to recent work.

The section General Contributions, includes historical and bibliographical studies, one, for example, by Laufmann on surgical haemostasis through the ages; and also papers recording the professional experiences of members of the Medical School in Italy and India.

The *Journal of the American Medical Women's Association* is another American journal linked to a medical institution, the New York Infirmary. This number (vol. 2, no. 3, 1947) has been contributed by the staff of the Infirmary; the scientific section includes articles on intra-uterine irradiation, the Rh factor in obstetrics, child guidance, a symposium on recent advances in therapy, and case reports.

The feature papers describe the history of the Infirmary, its traditions and present needs. It is well produced and documented, and includes a specially interesting feature in the list of current publications by women in medicine and in allied fields.

The following journals have also been received:

*Better Health* (London), vol. 20, no. 12, 1947

*Boletín de la Asociación Odontológica Argentina* (Buenos Aires), year 17, no. 199, 1947

*Bulletin of the Independent Biological Laboratories* (Kefar-Malal, Palestine), vol. 5, no. 3, 1947

*Chinese Journal of Nutrition* (Anshun, Kweichow), vol. 1, no. 1, 1946

*Hellinikiatriki* (Thessaloniki), year 17, no. 1, 1948  
*Medisiinari Lääketieteen kandidaattiseurau Julkaisu* (Helsinki) no. 3, 1947

*Népegészségügy* (Budapest), vol. 4, no. 1-2, 1948

*Oto-Noro Oftalmoloji* (Istanbul), vol. 1, no. 1, 1946

*Revista Stiintelor Medicale* (Bucharest), vol. 37, no. 1-2, 1948

*Salud* (Mexico D. F.), vol. 4, no. 4, 1947

*Türk Dişabipleri Cemiyeti Mecmuası* (Istanbul), vol. 24, no. 131-132-133, 1947

*Výživa Lidu* (Prague), vol. 2, no. 11, 1947

*Yaşamak Yolu Dergisi* (Istanbul), no. 131-133. [1946]

## A MEDICAL PUBLISHER

Messrs. E. & S. Livingstone of Edinburgh, the well-known medical and scientific publishers, inform us that they have now opened a London office at 45 Lincoln's Inn Fields, London, W.C.2, where medical men desirous of inspecting the firm's publications are assured of a warm welcome.

# Historical Notes

1227

## PIERRE JANET (1859-1947)

The emergence of scientific psychology in the second half of the nineteenth century constituted a kind of intellectual epic. With this movement the name of Pierre Janet is indissolubly associated and due tribute is paid to this great French psychologist in *La Presse Médicale* for 23 August, 1947 (55, 561-562).

Pierre Janet was born in Paris on 30 May, 1859, and, after obtaining his "agrégation" in philosophy at the age of 23, taught for seven years at Le Havre. At the same time he worked at the municipal hospital where he was put in charge of a ward of neurotic cases; here he began his researches on hypnotism and the lower forms of mental activity, which formed the subject of his philosophy thesis, *L'automatisme psychologique*. This revolutionary attempt to apply hypnotism to psychology raised a storm on its presentation at the Sorbonne on 21 June, 1889. Soon after, he obtained a Paris appointment, and continued to lecture on philosophy while completing his studies in medicine and taking his doctor's degree. He then became head of the psychological laboratory at the Salpêtrière, where he worked first under Charcot and later under Raymond. In 1895 he began deputizing for Ribot as professor of experimental and comparative psychology and was officially appointed to the Chair in 1902. He occupied this position until 1934.

Janet's teaching was based on his minute observation of cases. He always took detailed notes of everything said by the patient and of every reaction, and classified his voluminous case-records like a hotanical collection, habitually referring to them as his "herhier". Most of his lectures were collected into book form and constitute the basis of his published works; some of the more important of these are: *L'état mental des hystériques* (1893), *Les obsessions et la psychasthénie* (1903), *Les médications psychologiques* (1919), *La médecine psychologique* (1923) and *De l'angoisse à l'extase* (1926-28). His teaching acquired a great reputation abroad, particularly in North America, where his influence was comparable only to that of Georges Dumas in South America.

The ruling idea throughout Janet's work—to establish a hierarchy of mental function based on *pathological psychology*—shows the influence of Ribot, with whom Janet came into contact early in his career. Ribot had been one of the first to apply scientific methods to psychology and, in particular, to obtain data valid for both disease and health from the analysis of mental disturbances, and it was this method which Janet adopted as the basis of his work. He maintained that there are two distinct forms of mental function: *automatic* or *conservative activity*, limited to reproducing the past, and *synthetic activity* which combines existing phenomena into new phenomena quite different

from their component parts. The first activity is repetitive and the second creative. Normal thought is composed of both forms, but in weakened psychological conditions the synthetic activity gives way to the automatic.

Janet was a doctor as well as a psychologist. His name is linked with the syndrome of psychasthenia, which he was the first to differentiate and describe. His *La médecine psychologique* summarizes his experience as a psychotherapist. In this field he surpassed all his predecessors in the use of hypnosis and was at the same time one of the forerunners of the psychoanalysts. He made important observations on the cure of hysterical hypermnesia which led up to the psychoanalytic conception of "transforming the unconscious into the conscious", but left it to Breuer and Freud actually to cross the threshold.

Janet found a source of satisfaction in his old age in following the rapid development of psychiatry; he lived to see many of his early ideas, which had been fiercely contested at the time, confirmed by modern methods of psychotherapy.

## WAYFARERS IN MEDICINE

The pathways of the medical pioneers, if not always smooth at the time of their first explorations, are easy and pleasant for those who follow by the comfortable process of imaginative reading. Our guide, on the occasion under review, is a well known Dublin surgeon, and editor of the *Irish Journal of Medical Science*, Mr. William Doolin. He is familiar with the ground, and the wayfarers are all old friends of his. Although each of the twenty-six essays is complete in itself, the book preserves a chronological order, so that we pass from Imhotep to Sir Robert Jones, with such pleasant companions as Vesalius and Montaigne and Descartes and the less known Georges Mareschal, surgeon to Louis XIV. We accompany Amroise Paré on some of his "Journeys in Divers Places", we travel with Laënnec between Paris and his beloved Brittany, and we follow the career of General Gorgas who, by his war on yellow fever, made it possible for engineers to complete the Panama Canal and thus to facilitate still wider means of voyaging and wayfaring. Nevertheless this book is not a mere tissue of biographies, as a glance at the chapter titles will reveal.

The chapter on "Medicine and the Trade Routes" shows how the healing art followed the Moslem Empire in its westward march, and among other topics of interest, from which it is hard to make a selection, are "The Anatomist in Art", "The Resurrection Men", and "A Patient of the Renaissance", the last-mentioned being none other than Benvenuto Cellini, appearing in a guise which may be new to some readers. One of the most interesting chapters is that which deals with the history of lithotomy and, in particular, with Mr. Pepys and a number of other

<sup>1</sup> [For particulars see Book Reviews.]

writers who have recorded their trying experiences as subjects of "the stone". In the 16th and 17th centuries it was not uncommon to spread the news of a successful, or unsuccessful, operation by a broadsheet, or "Flugblatt", as it was termed in Germany, the home of such publications. The leaflet was often illustrated by a copperplate engraving of the stone. Its weight and measurement were also given, so that we have exact pathological records of the malady, which was then so common. The illustrations of this chapter, eight in number, are perhaps the most interesting in the book, although in general the reproductions are poor, being too small and indistinct to be of real value. Nevertheless the book is so attractively written that even without the plates it would have been most pleasing. It is sure to draw many readers, and it will amply prove that in medicine a study of the past is a most useful background to the practice of the present.

Douglas Guthrie

1229

## THE CHAMBERLENS AND THE MIDWIFERY FORCEPS

The story of the Chamberlens and of the invention of the midwifery forceps has often been told, but it is so remarkable that Dr. Radcliffe's little book<sup>1</sup> is sure of a warm welcome from all students of medical history and, indeed, from many members of the general public who will appreciate a new account of a most intriguing episode in history. So far as the Chamberlens are concerned, this book adds little, if anything, to the information provided by J. H. Aveling's book of 1882 or by such standard works as those of Herbert Spencer and Kedarnath Das; but Dr. Radcliffe gives an extremely good account of the later development of the obstetric forceps, with special reference to the contributions of three Essex surgeons—Edmund Chapman, William Gifford, and Benjamin Pugh. The work of Smellie, John Aitken, and John Burton ("Dr. Slop" of *Tristram Shandy*) and of the French and German pioneers is also dealt with, and altogether the book provides a most concise yet readable summary of the evolution of modern instrumental midwifery. The tangled personal history of the Chamberlens, beginning with Dr. William, the founder of the dynasty, who came to England as a Huguenot refugee in 1569, is here clarified. It is probable that William's son, Peter Chamberlen I (died 1631), was the inventor of the instrument that has preserved the family name. Hugh Chamberlen, Senior, was the chief exploiter of the secret and, by virtue of his position as accoucheur at the Court and by his contacts abroad, did most to spread the use of the forceps. The forceps themselves were lost to the world for more than a hundred years prior to 1813, when four sets were discovered in a box hidden under a floorboard at Woodham Mortimer Hall, near Maldon in Essex. This house was occupied by Dr. Peter Chamberlen III in the time of King Charles II, and it appears that the instruments were hidden by his widow. The secrecy which the Chamberlens maintained in regard to the nature of their invention has been strongly condemned, and poetic justice has led some historians to attribute the invention to other obstetricians. Strong claims have been made on behalf of John Palfyn, a surgeon of Ghent; but it is known that Palfyn visited London and it is probable, as Dr. Radcliffe maintains, that he heard of the forceps through one of the Chamberlen family and devised similar instruments of his own on his return to the Low Countries. Dr. Radcliffe also gives a graphic account of Hugh Chamberlen's visit to the Hôtel Dieu at Paris and of his unsuccessful attempt to deliver one of the great Mauriceau's patients—a rachitic cripple—by means of his forceps. He also deals with Chamberlen's later days at Amsterdam, where he is said to have sold the family secret to certain Dutch surgeons.

One or two slight errors may be noticed: the ill-fated Sir Richard Croft is referred to as Crofts, and the great French obstetrician Mauriceau appears throughout as Moriceau. The very interesting Chamberlen family tree given on page 72 could well be extended by reference to Peter Chamberlen's will as printed on pages 9-14 of Aveling's book on *The Chamberlens* (1882). This gives information concerning his wife Anne Cargill. Neither Aveling nor Dr. Radcliffe mention Peter Chamberlen's son David (1590-1618), who studied medicine at

Leyden, became a ship's surgeon in the East Indies Fleet, and bequeathed "fifty Jacobus pieces in gold" to Marischal College, Aberdeen (Smith, 1932).

## ST. THOMAS'S HOSPITAL 1106-1947

This short account<sup>1</sup> of the development of one of London's most famous hospitals is intended for the layman rather than the medical historian, for in 72 pages it is not possible to do more than touch upon a few of the outstanding persons and events associated with the life of so old a hospital.

Once more the claim is made that St. Thomas's is the oldest of the London hospitals, although the author is unable to present any fresh evidence; all that can definitely be claimed is that, even before the Norman Conquest, there existed a religious establishment on the south bank of the river Thames adjacent to London Bridge, upon the site of which St. Thomas's Spital was standing in 1173. This site was continuously occupied by the hospital until the removal to Lambeth in 1871.

In so small a book it is possible to mention only a few of the medical giants who walked the hospital and taught in it in the past, but the author might have devoted a little more of his valuable space to this aspect of the life of the hospital, and less to nursing, which is very fully reported, especially in the second half of the book. Much space is devoted to the life of Florence Nightingale, even before she became connected with the hospital; of the 49 illustrations, 4 depict Miss Nightingale and altogether 10 are concerned with nursing. Of the remainder, 16 have no connexion with the hospital and only 3 consist of portraits of eminent St. Thomas's men (Cheselden, Mead and Sir Astley Cooper—the last named incidentally being more concerned with Guy's Hospital, to which he was full surgeon). An appropriate companion portrait to that of Dame Lloyd Still would have been one of the late Sir Arthur Stanley, for so many years, and despite much infirmity, the hospital's devoted Treasurer; he is not even mentioned. Sir Cuthbert Wallace, Sir Percy Sargent, W. Rowley Bristowe (*sic*), Sir Maurice Cassidy and Sir George Makins are mentioned only by name; much could have been written about each one of them. We look in vain for a word about the Ballances, Shattock, Mellanby, Sherrington, to name but a few who spring to mind, although space is found for a story about Keats and a note on Mr. Somerset Maugham, both of whom learned their medicine at St. Thomas's but made their mark in other fields.

While it is true that no hospital has contributed more towards raising the status of nursing in this country, it has done so only during the last 80 years—since the advent of Miss Nightingale. On the other hand it has been a hospital for almost a thousand years and its physicians and surgeons have made many fundamental contributions to medical science. There should, for instance, have been room for a story of Cheselden's operation for stone; instead he is described as St. Thomas's "greatest surgeon" who "specialized in anatomy and became a leading oculist as well".

Nevertheless, Mr. Graves gives a most interesting account of the hospital during its long life and has obviously taken great pains to verify his facts. When he approaches the period of the recent war he is on firmer ground. He gives a vivid account of the grave damage caused to the hospital by air-raids, and of the evacuation of much of the hospital and all the medical school to Surrey. He is able, too, to include some photographs showing the extent of the damage sustained, but he is quick to point out that, severely as the war has dealt with this great hospital, it has at least given an opportunity for rebuilding what was a fairly modern hospital on even more modern lines. He outlines the plans for future reconstruction and closes his story with the hope that nationalization will not affect the service of the hospital or the patients' faith in it.

The illustrations are beautifully reproduced, and 8 are in colour. In preparing the book, Mr. Graves has obviously obtained much

<sup>1</sup> [The secret instrument. For particulars see Book Reviews.]

<sup>2</sup> [For particulars see Book Reviews.]

of his information from the three-volume *History of St. Thomas's Hospital*, and from *St. Thomas's Hospital Gazette*, the one written by and the other founded by, the late Professor F. G. Parsons; yet we look in vain for the author's acknowledgement to one who laboured for several years to produce the only comprehensive history of the hospital.

L. T. Morton

1231

## THE STORY OF QUININE

A gaudy jacket, which promises "romance, bloodshed, and the glitter of gold" in a form comparable "to the most highly imaginative fiction", is a truer indication of the publisher's aim than it is of the author's, and it would be regrettable if this disguise were to deter the serious reader from approaching a work which is obviously the product of considerable literary research. Our judgement of the factual basis of Mrs. Duran-Reynals' history of quinine<sup>1</sup> is further prejudiced by the omission of "an excellent bibliography which includes many obscure and little-known primary sources", an item which, so Professor Fulton tells us in his preface, was included in the American edition of 1946.

This book is indeed a "pageant" rather than a history, for the author has chosen to illuminate a carefully selected series of dramatic events, each a milestone in the history of the exploitation of one of the most important drugs in the pharmacopoeia, and one which was described by Ramazzini as being capable of transforming the art of medicine as drastically as gunpowder transformed the art of war.

Introduced into Europe about the year 1639, its true value was for long a subject of violent dispute, while the fact that it was sponsored by the Jesuits brought it into the arena of religious controversy. The familiar story of Sir Robert Talbot, whose empirical use of the powdered bark won him fame and royal patronage in both England and France and secured its introduction into the official Pharmacopoeia of 1677, is followed by an account of the expedition which enabled La Condamine to give the first botanical description of the tree itself. The pitiful career of the English botanist Richard Spruce, who, on the slopes of the Andes, collected the seeds from which were grown the "red cinchona" plantations of India, the source of *totaquine*, is paralleled by the heroic gesture of the Indian, Manuel Incra, which brought eponymous fame to his master Charles Ledger (*Cinchona ledgeriana*) and led to the establishment of the great "quinine empire" of the Dutch in Java. In the concluding pages of the book we are given the story of the political and commercial hucksters, who "rigged the market" in order to maintain prices, restricting output of the previous drug while less than one-half per cent. of malaria sufferers—who comprise nearly a half of the world's population—were able to benefit from it. That is ironical enough, but it is—or was—an economic commonplace.

There is tragedy, in every sense, as well as irony, in the chequered history of cinchona, and nowhere is this so persistent and unyielding as in the career of the great South American naturalist José Celestino Mutis, and the establishment of "The Botanical Institute of the New Kingdom of Granada" at Bogotá. This, the first genuine scientific institution in the New World, was destroyed in the violence of counter-revolution, its director, Caldas, shot as a rebel, and the whole of its scientific documents, drawings and manuscripts, including the results of Mutis's life-work, seized by Spanish troops and shipped to Madrid, there to moulder unopened until the present decade. The story of this "great failure", which is comparatively unknown in this country, is undoubtedly the most valuable chapter in this book.

The writing is of the dramatic, occasionally sensational kind, but it is not unpleasant and the historical details are generally accurate. A few errors call for correction however. The *Schedula romana*, described as "a hastily written manual", was really a simple leaflet giving instructions for the use of the drug. The latter was first administered in England not in 1658, but certainly before 1655 by John Metford, a Northamptonshire physician whose case-book is now in the British Museum. Quinine, an alkaloid extract of cinchona isolated by Pelletier and Caventou in 1820, is confused anachronistically with the bark itself. The general medical background is hazy and sometimes wildly erroneous, as in the statement on page 71 that, in the year 1666, Harvey and Vesalius "had been officially repudiated

and it is doubtful whether the rank-and-file practitioner knew much about them."

However, if Mrs. Duran-Reynals has not given us the substantial work of irreproachable scholarship which the history of cinchona merits, we must acknowledge that she has written the most lively and stimulating sketch yet offered to the public.

F. N. L. Poynter

1232

## ANONYMUS LONDINENSIS

*Anonymus Londinensis* is the name given to a medical papyrus in the British Museum. It was first described by Sir Frederick Kenyon in 1892. An elaborate edition of the Greek text was brought out by Hermann Diels in the following year, and a German translation, with notes, by Heinrich Beckh and Franz Spät was published in 1896. The papyrus probably dates from the second century A.D., and represents a copy, made for private use, of an earlier work. In this edition<sup>1</sup> the Greek text of Diels has been reprinted together with an English translation, based on an amended text, and valuable notes. Dr. W. H. S. Jones, President of St. Catherine's College, Cambridge, who is responsible for the present work, is a classical scholar who has for many years made a special study of Greek medicine. He is already well known to medical historians as the author of a monograph on *Malaria and Greek history* and as co-editor, with the late Dr. E. T. Withington, of the *Loeb Hippocrates*. The translation is the part of the book to which Dr. Jones has devoted practically his whole attention. The original is full of almost insuperable difficulties, and few more competent authorities could have been found to undertake their solution.

The work known as *Anonymus Londinensis* consists of over 1,900 lines, and is divided into three parts, dealing with (1) definitions, (2) the etiology of disease, and (3) the history of physiology. A great part of the work appears to have been taken from the *Menoneia*, a collection of medical opinions attributed by some to Aristotle, but really written by Aristotle's pupil Menon. Some authorities think that the original of *Anonymus* was a series of extracts made by a student from Alexander Philalethes, a pupil of Asclepiades, who flourished at the beginning of the 1st century A.D., and is the latest authority mentioned in the text. Another theory, maintained by Max Wellmann, is that the author was Soranus of Ephesus, a physician of the 2nd century A.D. and a leading authority on midwifery and the diseases of women. The conclusion of Dr. Jones is that the papyrus is a copy, made by a medical student, of lecture-notes also made by a student, and containing elements derived from all the above-mentioned sources.

The first part of the work deals with the definition of such terms as "life," "soul," "bodily affection," and "psychic affection." Part two is concerned entirely with the causes of disease, which are reduced to two classes: (1) residues from food, and (2) disturbances in the blendings of the elements composing the body. Of the twenty medical authorities quoted, seven were unknown before the discovery of this papyrus. This section also contains a long account of Plato's medical views. The third section deals with the history of physiology after 300 B.C., from Herophilus to Alexander Philalethes, and is the most interesting as regards subject matter. A brief account of human anatomy is followed by a discussion of ideas of vitality and motion, nutriment, and the various emanations from the body. Special attention is paid to digestion, to the veins and arteries, and to the invisible "pores". According to Dr. Jones, certain statements in *Anonymus* provide the only reliable testimony for the doctrine of the historical Hippocrates, a point of considerable importance in view of the sceptical attitude which now prevails in regard to the works of the Hippocratic Corpus. Many of the problems posed by *Anonymus Londinensis* may never be finally settled, but as Dr. Jones remarks, "the Hippocratic problem, like the Homeric problem, cannot take from us our heritage."

In two supplementary essays Dr. Jones deals with the nature of Greek thought and the nature of Greek medicine, and gives a masterly exposition of the relations between medicine and philosophy in the ancient world.

## ALLERGY

### 1233 Synopsis of Allergy

Harry L. Alexander. Second Edition, London, Henry Kimpton, 1947. 255 pages; 22 figures. 20 x 13 cm. £1

(i) Historical; (ii) atopy; (iii) bronchial asthma; (iv) hay fever; (v) atopic rhinitis; (vi) gastrointestinal allergy; (vii) headache, conjunctivitis, other atopic disorders; (viii) allergic dermatoses; (ix) physical allergy; (x) drug allergy; (xi) serum allergy; (xii) bacterial allergy; (xiii) vascular allergy. Appendix. References.

Since the first edition of this book was published, the introduction of anti-histamine drugs has opened up a promising line of advance in the therapeutic field in allergic disorders. It may be that this fact has given to the physician an added interest in allergy. Many of the books written on the subject tend to be overburdened with the theoretical aspects rather than the known facts. A small book such as Professor Alexander has produced should satisfy the needs of a large number of people who require an up-to-date review of the modern trends of knowledge in the allergic disorders.

The author begins the book, after a brief historical survey, with some general considerations of allergic diseases. He stresses throughout the book the possible limitations of the skin test, which is of value so long as the limitations are understood. The differentiation of asthma into what is called atopic and intrinsic may be new to some workers. In atopic asthma there is often a positive personal and family history of atopic disorders and the skin tests are usually positive. This type, which usually begins in the 1st or 2nd decade, may react to environmental control. Intrinsic asthma on the other hand usually has no family or personal history of atopic disorders, the skin tests tend to be negative, the age of onset is after the second decade and the prognosis, even with proper treatment, is uncertain. The chapter on asthma has a lot of sound advice on possible lines of treatment.

The section on hay fever is the best in the book. In the USA the importance of ragweed as well as the grasses, as a cause of hay fever, may make it necessary for the patient to start treatment in February and continue until September. It is not surprising therefore that the author considers perennial treatment gives better results than pre-seasonal. Co-seasonal treatment is considered an emergency treatment rather than one of choice. More recent works, since this was written, suggest that co-seasonal treatment with a suitable anti-histamine drug gives results that are as good as any other method used.

The last nine chapters of the book deal with other aspects of allergy not related to asthma or hay fever. It is impossible in a synopsis not to be dogmatic, but even those workers whose opinion the author does not share are given more than adequate mention. In a book where such a wide field of knowledge is covered there are sure to be some gaps. The index is not full enough. A better photograph than that shown of atopic dermatitis should be found. British readers will be surprised to find no mention of the Noon unit in the standardization of extracts.

However, these are minor criticisms. The book can be strongly recommended as an easily-read account of modern ideas in allergy. There is a short list of references at the end of the book for those who require a more-detailed knowledge of allergic work.

A. W. Frankland

## ANAESTHESIA

### 1234 A Synopsis of Anaesthesia

J. Alfred Lee. Bristol, John Wright & Sons, Ltd., 1947. vi + 254 pages; 42 illustrations. 19 x 13 cm. 12s. 6d. [£0.625]

(i) Notes on the history of anaesthesia; (ii) respiration; (iii) pre-anaesthetic care and preparation; (iv) premedication; (v) inhalation anaesthesia; (vi) agents for inhalation anaesthesia; (vii) the closed circuit; cyclopropane; controlled respiration; (viii) nitrous oxide anaesthesia; (ix) accidents of inhalation anaesthesia and how to treat them; (x) gases used in association with anaesthesia; (xi) endotracheal anaesthesia; (xii) rectal anaesthesia—basal narcosis;

(xiii) intravenous anaesthesia; (xiv) analeptics; (xv) spinal analgesia; (xvi) regional anaesthesia; (xvii) refrigeration analgesia; (xviii) choice of anaesthetic as influenced by type of operation; (xix) choice of anaesthetic and methods as influenced by general condition of patient; (xx) the use of curare in anaesthesia; (xxi) shock; (xxii) anaesthesia in thoracic surgery; (xxiii) the complications and sequelae of anaesthesia; (xxiv) explosion risks in anaesthesia; (xxv) management of the unconscious patient; (xxvi) anaesthetic records; (xxvii) anaesthesia and analgesia in labour. Index.

This book would appear to be as good as any synopsis can be. It contains a précis of all the essentials of anaesthesia and analgesia, presented with a balance and lack of bias which is most refreshing.

Any book of this nature is meant for the student who has already read through a textbook and who has a sound knowledge of the subject by practical experience. He can then use it to revise any section quickly or to look up any facts or figures which he may have forgotten. On the other hand, the limitations of a synopsis should also be realized. The matter presented must of necessity be largely composed of stark statements without explanations or references. It is thus unsuitable for the novice and must not be regarded as a "cram-book" which offers an easy short-cut to knowledge.

The production of the book is excellent and the use of many different types breaks up the pages in an agreeable manner.

Proof-reading must have been exceptionally thorough, as only one error was detected by the present reviewer. On page 131, the strength of the intravenous drop of adrenaline is given as 1 in 125,000 instead of 1 in 250,000.

The book can be recommended without reserve to the class of reader for whom it is written.

C. Langton Hewer

### 1235 Curare: its History, Nature, and Clinical Use

A. R. McIntyre. Chicago, The University of Chicago Press; London, Cambridge University Press, 1947. vii + 240 pages; 25 illustrations. 25 x 17 cm. £1 7s. 6d. [£1.375]

(i) Curare and its meaning; (ii) the early history of curare; (iii) the first witnesses; (iv) botany; (v) chemistry; (vi) early experiments with curare; (vii) the actions of curare on nerve and muscle; (viii) theories of curarization; (ix) effects of curare on the circulation and respiration; (x) effects of curare on the viscera; (xi) absorption, excretion, and toxicity of curare; (xii) miscellaneous effects of curare; (xiii) curare and the central nervous system; (xiv) the clinical use of curare; (xv) conclusions and speculations. Addendum. Subject index. Author index.

This is an authoritative monograph sponsored by the University of Chicago Committee on Publications in Biology and Medicine; the author is Professor of Physiology and Pharmacology at the University of Nebraska.

The history of the discovery of the south american arrow poison is narrated with meticulous accuracy and with frequent quotations from the pioneer naturalists.

The various plants from which the crude curare has been extracted are fully described and illustrated in the chapter entitled Botany.

The pharmacological effects of the alkaloid on the various systems of the body are described in great detail and incorporate the research work carried out by the author with his colleague Dr. A. E. Bennett over a period of six years. It is interesting to note that Dr. McIntyre does not regard the electrical and biochemical theories of neuromuscular transmission as being antagonistic but complementary.

Only one chapter is devoted to the clinical use of curare and only four pages to its applications in anaesthesia but nevertheless the book is probably the most exhaustive source of information extant about the drug as a whole and can confidently be recommended.

## CANCER

### 1236 Cancer of the Breast

Duncan C. L. Fitzwilliams. London, William Heinemann Medical Books, Ltd., 1947. vii + 199 pages; 24 illustrations. 22 x 15 cm. £1 5s. [£1.25]

(i) The nature of the disease; (ii) spread of cancer; (iii) early diagnosis; (iv) clinical signs; (v) etiology and pathology; (vi) the treatment of carcinoma: early cases treated by local removal; (vii) treatment by operation; (viii) treatment by radium; (ix) treatment of late cases; (x) clinical types; (xi) other forms of treatment; (xii) X-ray therapy in carcinoma of the breast. Index.

## THE MEDICAL RESEARCH COUNCIL

**Medical Research in War: Report of the Medical Research Council for the years 1939-1945.** Cmd. 7335. Price 7s. 6d. net. By post 7s. 11d. This is the Report to Parliament of the Council's activities during the war years. It is in direct succession to previous Annual Reports, and consists of a summary account of work promoted or sponsored by the Council and by their Industrial Health Research Board during the period under review, together with a full bibliography of published papers.

**Fatty Liver Disease in Infants in the British West Indies** by J. C. Waterlow. (1948). *Special Report Series No. 263.* Price 2s. net. By post 2s. 2d. This report describes and defines a serious nutritional disease of infants in certain tropical areas. Other work in this field is critically surveyed, and an effective link is established between the experimental effects of protein deficiency in animals and the clinical condition seen in these infants.

**Chemotherapeutic and Other Studies of Typhus** by M. van den Ende, C. H. Stuart-Harris, F. Fulton and J. S. F. Niven, with others. (1946). *Special Report Series No. 255.* Price 12s. 6d. net. By post 12s. 11d. The trial of two chemotherapeutic agents in the treatment of epidemic typhus fever in man is here described, together with a detailed account of the clinical forms of the disease and the laboratory findings. There is also included a number of important experimental studies on the immunology of typhus.

## SECOND EDITION

# *The Venereal Diseases*

*A Manual for Practitioners and Students*

By JAMES MARSHALL,

M.B., B.S., M.R.C.S., L.R.C.P.

This edition has been revised and new material added. The latest information on the use of penicillin in the treatment of the venereal and allied diseases is incorporated. The sections on rapid arsenotherapy and on non-gonococcal urethritis have been rewritten and expanded to include the recent advances. This is essentially a practical book for students and practitioners, and the technical details and methods described are mainly those which can be carried out in general practice. Illustrated with 8 coloured plates and diagrams  
21s. net.

**Macmillan & Co., Ltd.**

The author expounds here in colloquial language his own ideas and experience of mammary cancer, and amplifies the text by case-notes. His advocacy of a more restricted operation than was the former custom is of particular value. In the past, surgeons have tried to overtake the spread of cancer by ever widening the field of operation. Modern inquiries, however, have shown that x rays can deal with the remoter extensions of cancer better than surgery alone; and radiotherapy after operation is therefore coming rapidly into general and effective use. The case-notes properly record mistakes occasionally made by the general practitioner or the surgeon when consulted by a patient with cancer of the breast. Tragic errors sometimes occur in this difficult field and the more that is known about them the less often will they happen. Procrastination is a great evil. Once cancer has begun it must be presumed to be spreading all the time, and the need for treatment is urgent. Mr. Fitzwilliams mentions the delay caused either by the patient's reluctance to consult her doctor, or by the doctor's hesitation to refer her to a surgeon; but he gives little attention to the prolonged interval which so often elapses between the advice to undergo an operation and its performance. This at present is part of a troublesome national problem, because of the paucity of hospital accommodation, and any detailed information about it would be acceptable.

Apart from the useful case-notes and description of surgical technique, the book contains several dogmatic statements which are questionable, and in some instances appear to the reviewer to be misleading. This comment may be illustrated by the quotations which follow:—

I remember reading of some experiments which showed that if carcinogenic substances were painted on the skin of an animal and a carcinoma established, and if that carcinoma was excised locally before dissemination had taken place, no subsequent painting of the skin would start a similar carcinoma. If this is true, the laboratory bears out what we see clinically, and leads us to believe that the growth of one carcinoma confers an immunity on the host against another similar growth starting.

Referring to involvement of the lymph nodes he states:

It should be realised that the importance of the lymphatic stage was only established at the beginning of this century . . .

Although the spread of cancer by the blood-stream has been known for more than a hundred years we are told that

. . . the clinicians have so far failed to realise its significance. The teaching in most medical schools remains much the same as when I was a medical student, namely, that sarcoma spreads by the blood stream, but carcinoma spreads by the lymphatics.

Discussing early diagnostic signs and referring to retraction of the nipple, he states:

This is a useful help in diagnosis, though unfortunately it is absent in the majority of cases.

And in a brief discussion on etiology, we read:

When our accepted theories of heredity have been so shaken by the recognition of the doctrines of Mendel, it is very difficult to be positive about heredity.

After mentioning the milk factor of mammary cancer in mice, he says:

In any case so few human mothers now suckle their offspring that the matter is hardly worth considering.

The illustrations on pages 87 and 88 and facing page 92, showing suggested arrangements of radium needles for the treatment of mammary cancer, appear to the reviewer to disregard the principles of dose-distribution on which such treatment must be founded.

An excellent chapter on the principles of x-ray therapy by Dr. Alice Ross is an addendum to this little volume.

Though it can be recommended to surgical technicians of experience who can form their own judgements, the book contains so many questionable statements that it cannot be regarded as a sound guide to the student or as an accurate exposition of the science of british surgery.

Harold Burrows

## 1237 Bioterapiya Zlokachestvennikh Opookholay

N. G. Klueva & G. I. Roskin. Moscow, Akademia Meditsinskoy Naook, 1946. 224 pages; 97 figures; 19 tables. 22 x 15 cm.

(i) Introduction. (ii) Inhibitors of malignant growth: mouse carcinoma and human carcinoma; general remarks on tumour-inhibiting substances; metals, lead; dyes as chemotherapeutic substances; heptyl aldehydes; carcinogenic hydrocarbons; immunotherapy; yeast. (iii) Bacterial products: mode of action; experimental and clinical studies on polysaccharides from *B. prodigiosus*. (iv) The action of toxins from *Corynebacterium diphtheriae* and *B. tetani*: treatment of transplantable tumours; treatment of spontaneous mouse tumours by diphtheria toxin. (v) Protozoan infections and transplantable tumours: Try-

*panosoma cruzi* infection and the growth of transplantable tumours; the specificity of *T. cruzi* action on transplantable tumours; the effect of *T. cruzi* and other protozoan endotoxins; *T. cruzi* and transplantable sarcoma; trials with "K-R" substance; the active part of the "K-R" substance; trypanosoma vaccines; vaccines prepared with alcohol, with metaphen; products obtained by lysis of *T. cruzi*; experiments with the "K-R" substances of the 3rd, 4th and 5th modifications. (vi) Histological and cytological changes in tumours induced by the carcinolytic substance; the action of *T. cruzi* on Ehrlich adenocarcinoma and Crocker sarcoma; the effect of the "K-R" substance on Ehrlich carcinoma and on spontaneous tumours in mice; histological and cytological changes in Crocker sarcoma induced by *T. cruzi* and the "K-R" substance. (vii) Summary and conclusions from experimental investigations. (viii) Preliminary clinical studies on the anti-tumour substance from *T. cruzi* ("K-R" substance); the purpose of clinical trials; description of cases; modifications of the "K-R" substance employed in clinical trials; carcinolytic syndrome; carcinolytic reaction and regeneration of normal tissues; the possibility of a cancer cure by the sole application of the "K-R" substance; the lytic reaction in various types of tumour tissue; induction of resistance in tumour cells and susceptibility of the body after repeated application of the "K-R" substance; relationship between the dose and the lytic reaction in tumours; mode of application of the "K-R" substance; subjective reaction after inoculations; local reaction; temperature; blood pressure; cardiovascular reaction; general reaction; preliminary results. (ix) Anti-tumour substance of *T. cruzi*: tropism and antagonism; properties of the anti-tumour substance from *T. cruzi*; mode of action of the "K-R" substance; treatment of Brown-Pearce carcinoma and its significance. (x) Conclusions. (xi) 133 References.

This is a monograph on the experiments carried out by Roskin and his collaborators on treatment of tumours with various bacterial and protozoal products.

It is felt that of the two main duties of the reviewer, description and criticism of the work, the first should receive foremost consideration in the present case. Hence an attempt will be made to acquaint the reader with the main points in the experiments and with the results described.

The book is divided into two parts. In the first, experimental, and in the second, clinical work is described.

The first part, preceded by a fairly comprehensive review of the many attempts to inhibit malignant growths, can be subdivided into a chapter devoted to the studies on treatment of tumours with diphtheria- and tetanus-toxins and a chapter on protozoan infections and tumours.

The treatment of transplantable Ehrlich carcinoma in mice with *B. tetanus* toxin gave complete regression of tumours in 19 out of 48 mice, and inhibition of tumour growth in 6 more mice, with an average decrease in tumour weight of about 5 times that of the control mice. Similar results were obtained with Flexner-Jobling carcinoma in rats and with Kritchevsky-Sinelnikov sarcoma in rats. Better results are claimed in the treatment of Ehrlich carcinoma with diphtheria toxin, where the dose and concentration play an important part. While treatment of Ca63 carcinoma in mice was disappointing, in Crocker's sarcoma the weight of treated tumours was 4 times smaller than that of the controls. The authors claim that diphtheria toxin inhibits the growth and induces the disappearance of tumours in a large percentage of animals, even in well-established tumours (of ten days' growth).

Diphtheria toxin was also employed in the treatment of 40 mice with spontaneous mammary tumours of various sizes. Unfortunately, the strain of mice is not mentioned, nor is the age of the tumours. Complete regression of tumours was recorded in 15 mice, diminution in tumour size in 18 mice, complete inhibition of tumour growth in 6 animals. It is a matter of regret that neither controls, nor data about the life-span of mice in which the tumours regressed, or the dosage employed, are mentioned. The experiments are accompanied by numerous drawings of mice with tumours and their progressive decrease in size is presented. The effect of the treatment is rapid: usually 7-14 days are sufficient to give complete regression of tumour growth. There are no histological descriptions of changes in tumour tissue induced by the treatment.

In the fifth chapter, on protozoan infections and tumours, experiments are described which date back to 1931. They were mostly carried out on mice with implanted Ehrlich adenocarcinoma. In an experiment in which 45 mice (strain not given) were infected with *T. cruzi* and at the same time implanted with Ehrlich carcinoma, the tumours disappeared in 30 mice, and tumour growth was greatly retarded in the 15 remaining mice. All the test mice eventually succumbed to the infection, but they lived longer than the control mice or the mice infected with *T. cruzi* but not implanted with tumours. In order to investigate the specificity of the *T. cruzi* effect on tumours, *Spirochaeta duttoni* and *Spirochaeta obermeieri* were tested against Ehrlich carcinoma, and *T. equiperdum* against a guinea-pig carcinoma (strain not stated), but they had no influence on tumour growth. The authors consider, therefore, the effect of *T. cruzi*

object of the series is to provide more-detailed analyses of important subjects than is possible in his Annual Statistical Reviews.

Dr. Stocks begins his study with a review of cancer mortality rates in various countries and the inferences made from them by previous writers on the subject. Marked differences occur between different countries in the mortality levels for cancer of certain sites, and the hypothesis that these can be explained by over-certification or incomplete certification in some countries is examined. Variation in mortality levels, however, is also to be observed within individual countries and this paper is primarily concerned with such variation in England and Wales.

Records of deaths over the last twenty years reveal that mortality from cancer of the stomach has shown little change amongst men between the ages of 45 and 64, but above this age the rate has increased by approximately 5%. Amongst women, on the other hand, stomach cancer has decreased generally. For all other sites combined the male rate has increased by 6 to 9%, compared with a decrease in the female rate of some 6%. Interesting features of the trend of lung cancer are the difference between the sexes, mortality having increased twice as much amongst men as amongst women; and the very great increase in certified mortality from this cause—the male rate being six or seven times as great now as it was twenty years ago.

For certain organs of the body important differences exist in mortality levels between administrative and geographical regions; for example, the proportion of deaths assigned to cancer of the respiratory organs to those of all sites is higher in London and the County Boroughs than in the Rural Districts. For cancer of the stomach, on the other hand, the position is reversed.

A significant correlation was found between comparative mortality from cancer of the stomach and certain environmental indices ( $r = 0.543 \pm 0.129$  with "persons per room" and  $r = 0.526 \pm 0.132$  with the "social class index") when the rates for males aged 45-64 in 30 large towns were examined. Cancer of the lung, in contrast, was not associated with environment in this way. Cancer mortality from 1921-30 amongst women aged 45-64 revealed that the highest comparative mortality (from cancer of the ovary, 116), and the lowest from cancer of the stomach, 82) were associated with the best social conditions. At the other end of the scale, the highest comparative mortality (from cancer of the stomach, 124 and uterus, 110), and the lowest (from cancer of the breast, 90 and ovary, 77), were associated with the worst social conditions.

Only the more striking correlations and contrasts have been mentioned above. In the sections on variations in mortality from certain sites, between social classes, environmental groups and other factors in England and Wales, Dr. Stocks discusses many interesting results, a full enumeration of which is not possible here. However, it is perhaps of interest to record the high negative correlation ( $r = -0.690 \pm 0.117$ ) found between mortality from lung cancer and hours of sunshine from the data of 20 towns.

The Metropolitan Boroughs of London provide a useful source of mortality data for an analysis of this nature in that a fair degree of uniformity of diagnosis, treatment, and climatic conditions is common to all. Further correlations revealed that amongst males aged 45-64 both cancer of the stomach and cancer of all sites except the stomach and lung were again highly and significantly associated with "persons per room". Again, cancer of the lung did not reveal this association. For women aged 45 and over, the standardized mortality rates from cancer of the stomach were highly correlated with the housing index ( $r = 0.715 \pm 0.094$ ), but with the same environmental index a high negative correlation ( $r = -0.779 \pm 0.074$ ) was found with cancer of the breast.

Mortality from some sites varied considerably between neighbouring boroughs in London and interesting contrasts emerged when the boroughs were grouped according to their source of water supply but "the curious correspondence in certain respects between cancer death rates and the sources of water does not prove that there is a causative connection".

In a foreword to the report the Registrar-General quotes the author as follows: "the purpose of this report is to present the statistical facts and point out any peculiarities in distribution and correspondences with other measurable factors which appear, so that all possible clues may be followed up by further study."

There is no doubt that this report achieves its purpose and it sets out the statistical facts in great detail.

## 1239 Entstehung und Früherfassung des Portiokarzinoms

Hansjakob Wespi. Basel, Benno Schwabe & Co., 1946. 183 pages; 95 figures. 23 x 16 cm. Sw. fr. 18.

(i) Problemstellung; (ii) Historisches zur kolposkopischen Methodik und Diagnose und zur Kenntnis der Frühformen des Portiokarzinoms; (iii) die histologischen und kolposkopischen Bilder der normalen und pathologischen Portio; (iv) Grundsätzliches zur Frage des beginnenden Karzinoms; (v) die Einteilung und Nomenklatur des Portiokarzinoms und der übrigen Portioveränderungen. 1. Teil. Die Früherfassung des Portiokarzinoms. (i) Einleitung; (ii) das beginnende und das ganz kleine Portiokarzinom; (iii) kolposkopische Erfahrungen am fortgeschrittenen Karzinom; (iv) Statistisches zur Frage der Krebsfrüherfassung; (v) Schlussfolgerungen. 2. Teil. Die Entstehung des Portiokarzinoms. (i) Einleitung; (ii) die verschiedenen Formen des Portioepithels und ihre Beziehung zum Karzinom; (iii) Beobachtungen zur Frage der Krebsentstehung; (iv) Schlussbetrachtungen. Literaturverzeichnis.

The early diagnosis and treatment of malignant disease is, without doubt, the most important problem in clinical practice today. The cervix of the uterus is exceptional amongst the common sites for the development of carcinoma because it can be examined visually without much inconvenience to the patient. It is obvious on theoretical grounds that if the cervix of a patient is examined sufficiently frequently the origin and development of carcinoma of the cervix should be traced. Hinselmann's technique of examination of the vaginal portion of the cervix under binocular vision at a magnification of about 10 diameters, combined with the reaction of the epithelium to such chemicals as iodine, acetic acid, silver nitrate and salicylic acid, was soon shown to be of great value in the interpretation of pathological changes. Much credit is due to Hinselmann for his description of the different types of epithelium and for his Rubrik system of histological types.

Dr. Wespi, working in the University of Zurich, has used Hinselmann's methods for many years and has collected together in this small volume some valuable and excellent results. If gynaecologists learnt the contents of the book and if they employed the Hinselmann technique, they should be able to diagnose carcinoma of the cervix in its earliest stages almost with precision. Not only that, but they should be able to identify suspicious areas which are now known to be precancerous in character, when the cervix should be removed by simple amputation. Indeed, if the Wespi-Hinselmann methods were used extensively, the incidence of carcinoma of the cervix would be reduced and cancer cases would be available for treatment in their earliest stages. The book is of very great value in addition to its application, for it contains an almost complete summary of the literature, and the theoretical problems are considered both in a scholarly manner and in sufficient detail. These problems are notoriously of immense difficulty, yet Dr. Wespi approaches them courageously and gives a reserved judgement when final proof is not available.

Dr. Walter Schiller has written to the reviewer to record his high appreciation of Wespi's book, and to say that an effort is being made to have the book translated and published in the USA. Without doubt it is one of the most important contributions that has yet been made to the study of early carcinoma in the human subject.

## CARDIOVASCULAR SYSTEM

### 1240 Die Klinik der energetisch-dynamischen Herzinsuffizienz

Robert Hegglin. Basel, S. Karger, 1947. 120 pages; 82 illustrations. 24 x 17 cm. Sw. fr. 19

(i) Einleitung; (ii) die energetisch-dynamische Herzinsuffizienz als Problem; (iii) die Feststellung der energetisch-dynamischen Herzinsuffizienz; (iv) experimentelle Untersuchungen; (v) Vorkommen der energetisch-dynamischen Herzinsuffizienz in der Klinik; (vi) die klinische Symptomatologie der energetisch-dynamischen Herzinsuffizienz; (vii) die prognostische Bedeutung der energetisch-dynamischen Herzinsuffizienz; (viii) die Ursachen der energetisch-dynamischen Herzinsuffizienz; (ix) die Therapie; (x) Schlussbetrachtungen. Literaturverzeichnis.

The steady advance in cardiological research leads to increased emphasis on the dynamic events in the heart. During the last decade the techniques of determination of cardiac output have

undergone rapid development. When these have been combined with pressure measurements within the heart, remarkable revelations have occurred. For example, we now know that the signs of heart failure may be present when the resting cardiac output is normal or high, and we have also acquired useful quantitative ideas on the degree to which the pulmonary arterial pressure is raised in emphysema. The field of cardiology is no longer limited by the anatomical boundaries of the heart.

Dr. Hegglin has produced a book which will interest all who wish to consider deeply the problem of the failing heart. He discusses the modern physiology of muscular contraction and points out that fatigued muscle has long been known to contract and relax slowly. If the failing heart reacted in this manner, we should expect prolongation of systolic contraction, which would show itself by an increased interval between the first and second sounds and a prolonged QT interval in the electrocardiogram, assuming that the electrical events in the ventricle were closely correlated with the mechanical. Most ordinary forms of heart failure, however, do not show prolongation of the QT interval with the exception of some cases of hypertension. Some forms of circulatory failure may show a heart reacting somewhat differently. Systole may be shortened, leading to a diminution of the interval between the first and second sounds, but this shortened mechanical systole may be followed by delayed relaxation shown in a prolonged QT interval. Dr. Hegglin has made an extensive study of the duration of systole in experimental conditions and also in a variety of clinical states. He finds, for example, that the QT interval may differ quite significantly from the interval between the first and second sounds recorded graphically, and this is quite pronounced in diabetic coma, where mechanical systole seems to be very considerably shorter than electrical systole. A similar state of affairs is seen in hepatic coma and in severe alkalosis. These conditions may be associated with a low blood potassium. Hypocalcaemia leads to prolongation of the QT interval and simultaneous lengthening of mechanical systole. Discrepancies between mechanical and electrical systole are also seen in pneumonia, septic conditions generally, Addison's disease, and hyperthyroidism.

This syndrome, which he calls energetic-dynamic insufficiency, is characterized by the absence of venous congestion, and the short interval between the first and second sounds may be recognizable on auscultation. Pulse is often rapid and small in volume, with a reduced blood pressure, and the heart size is normal.

The author discusses in detail the possible significance of all these findings. Certain similarities with veratrine poisoning are indicated. In relation to the chemistry of muscular contraction he points out the importance of potassium in the release of energy from adenosinetriphosphate, and recommends giving saline infusions and potassium chlorate (4 g. daily) by mouth in treatment.

This is a refreshing monograph, with factual detail closely argued and full of interest. It is gratifying to see attention being paid to the heart in a variety of metabolic disturbances. Such work is likely to break down the artificial barriers enclosing the "specialities" and to compel attention to the integrated physiology of the whole organism, which is the real province of the physician.

## 1241 The Peripheral Circulation in Health and Disease. A Study in Clinical Science

Robert L. Richards. London, E. & S. Livingstone, Ltd., 1946. xii + 153 pages; 104 illustrations. 25 x 18 cm. £1 1s. [£1.05]

(i) The anatomy and physiology of the peripheral vasomotor system; (ii) methods of study—with particular reference to the recording of skin temperatures; (iii) spontaneous variations in vasomotor activity; (iv) imposed variations in vasomotor activity; (v) occlusive vascular disease; (vi) the Raynaud phenomenon; (vii) peripheral nerve injuries; (viii) the immersion foot syndrome. Conclusion. Index of authors. General index.

In this monograph concerning the peripheral vascular system, Dr. Richards assembles information that he has gained as a result of clinical observations carried out to a large extent on cases with war-injuries. This is a study in clinical science, and no reference is made to treatment.

He deals in some detail with the anatomy and normal physiological responses and vasomotor reflexes of blood-vessels, and thereby indicates how they may be employed in assessing the circulation in a limb and the way in which they may be disordered in disease. As he rightly points out, no one clinical test is adequate by itself, and he stresses how, for example in the lower limb, reflex vasodilatation may not take place when the upper limbs are immersed in hot water even though the circulation be within normal limits.

He has also much to add that is of interest in the interpretation of skin-temperatures. His study of vascular changes associated with peripheral nerve injuries is instructive. He believes that tropic changes, formerly thought to be a specific sequel to division of peripheral nerves are, in fact, largely the result of disuse, as the same changes are seen if a limb is not actively utilized for any other reason. The "cold phase", which inevitably follows denervation, he attributes to a combination of postganglionic sympathectomy, subnormal metabolism in the part and no accumulation of the normal vasodilator metabolites. With regard to the etiology of the Raynaud phenomenon, no new explanations are offered, but the full discussion cannot fail to impress the reader how very unsatisfactory are the present concepts.

The book is attractively set out and well illustrated with photographs and diagrams and, with its comprehensive list of references at the end of each chapter, will prove informative, provocative and well worth reading by those with little or much experience in this field of medicine.

## DENTAL SCIENCE

### 1242 An Atlas of Dental Histology

Edgar B. Manley & Edward B. Brain. Oxford, Blackwell Scientific Publications, 1947. xi + 49 pages; 22 figures; 102 plates. 25 x 19 cm. 12s. 6d. [£0.625]

(i) Enamel; (ii) dentine; (iii) cementum; (iv) pulp; (v) periodontal membrane; (vi) alveolar bone; (vii) development; (viii) absorption; (ix) enamel cuticle (Nasmyth's membrane); (x) epithelial root sheath of Hertwig; (xi) gingiva; (xii) histological technique; (xiii) ground sections; (xiv) decalcified sections; (xv) staining methods.

This book is dedicated to the memory of Dr. A. W. Wellings, and is intended as a guide for the student in his laboratory work. It is obvious, from even a casual glance, that an enormous amount of work has gone into the production of such a range of specimens and photomicrographs. Every part of the tooth and its attachments is copiously illustrated and on the whole the reproduction is excellent. A book of this type will be of value to students generally, but in particular to those who have access to the authors' lecture notes. To the research worker and advanced student, this book may be somewhat of a disappointment in that the descriptive matter is far too short and the reader is left with a series of unanswered questions. It is felt that the lettering of the photomicrographs could be improved, as the white discs obscure an appreciable amount of the part of the specimen to which they refer, and that more arrows could be employed to advantage. A truly excellent photomicrograph (Plate 47) is shown of Von Korff's fibres, and the following plates illustrating the nerves of the pulp deserve high praise. In the section on Nasmyth's membrane, Plate 88, depicting ends of the enamel prisms at a magnification of 55, leaves much to the student's imagination. One has also seen better photomicrographs than that of an enamel cuticle, Plate 89, depicting the ends of enamel prisms.

A section is included on histological technique to fulfil educational requirements of the General Medical Council, but it is felt that this could have been improved if the typical staining reactions of the various stains listed were given. Staining reactions do vary, but their inclusion would be of considerable help to the junior student. As pointed out by Professor H. F. Humphreys in the foreword, it must be remembered that the book is intended to supplement and not supplant the textbooks. Nevertheless, it is hoped that when a second edition is called for a further elaboration of its present scope will be contemplated.

## 'Hanovia is prescribed'—

Fifty years ago Finsen of Denmark discovered that ultra-violet rays cured and prevented disease. For forty years Hanovia quartz lamps have been standard equipment for all medical and technical applications of ultra-violet radiation.

Hanovia lamps are high-pressure mercury arcs in self-starting electronic quartz tubes. Long experience and specialised skill assure their users of easy operation and guaranteed reliability, with constant high output. Their acceptance and distribution is world-wide. In medical scope, treatment with Hanovia is prescribed in treating deficiency diseases—debility, rickets, anaemia, etc.—most forms of tuberculosis, many skin diseases, and numerous special conditions.

We offer free informative literature on therapeutic and technical applications of ultra-violet radiation, prompt despatch of orders for equipment, and comprehensive service after sale. These facilities are available through accredited agents and dealers in most capitals throughout the world. Catalogues free on request from

## DERMATOLOGY

## 1243 A Practical Textbook of Leprosy

R. G. Cochrane. London, Geoffrey Cumberlege, Oxford University Press, 1947. xi + 283 pages; 174 figures; 1 plate. 25 x 19 cm. £2 2s. [£2.1]

(i) Introduction; (ii) etiology; (iii) epidemiology; (iv) pathology; (v) diagnostic and other serological tests; (vi) signs and symptoms; (vii) classification and technique of examination; (viii) atypical lesions and the development of lesions; (ix) differential diagnosis; (x) reaction in leprosy; (xi) lesions of the nose, ear, mouth and throat; lesions of the eye; (xii) treatment of leprosy; (xiii) treatment of leprosy (continued); (xiv) treatment of leprosy (continued); (xv) treatment of neuritis in leprosy; (xvi) treatment of eye, nose and throat lesions; (xvii) treatment of trophic ulcers; (xviii) A. Treatment of syphilis in leprosy; B. Treatment of certain concomitant skin affections; (xix) A. Prognosis; B. Criteria of discharge and after-care; (xx) prevention of leprosy; (xxi) prevention of leprosy (continued); (xxii) practical methods of leprosy control. Appendices. Bibliography. Index.

As medical secretary to the British Empire Leprosy Relief Association and as Chief Medical Officer of the Lady Willingdon Leprosarium in Madras, the author has had a long and varied experience of leprosy. He has embodied that experience in the present work, which will be of interest to all leprologists. His reason for writing it is that he thinks that "... a practical textbook on leprosy would fill a gap between the type of book which deals largely with the theoretical aspects of the subject and the smaller pamphlets." In fact the text of his book is much longer, and unfortunately twice as expensive, as the standard English book on leprosy, by Rogers & Muir. It is somewhat uneven, for only two pages are devoted to the history of the disease and four to its etiology.

Epidemiology is rather more fully dealt with on modern lines, with emphasis on the low-age incidence, the great infectivity of the lepromatous type of the disease, and on the good prognosis of the tuberculoid form, the characters of which are illustrated in the pathological section by the author's photomicrographs. The prognostic value of the lepromin test and the want of any reliable serum diagnosis is brought out.

By far the best and fullest section is that containing well-illustrated clinical descriptions in which the important early symptoms are given special attention and the differential diagnosis of the different types of the disease is emphasized. The classification adopted by the Leonard Wood Memorial Conference on Leprosy (Cairo Conference, 1938) is used with some modifications. Atypical lesions are described in a separate chapter and are regarded as rare and intermediate between tuberculoid and lepromatous cases. Leprosy reactions are fully described and seven chapters are devoted to treatment, including that of the nose, throat and eye. The author relies on chaulmoogra preparations, but differs from most recent authorities in disparaging the use of sulphones, which have yielded such remarkable results in resistant lepromatous cases in the hands of Muir and of Louisiana workers.

The remaining chapters deal with preventive measures and are based mainly on the author's experience in Madras. Apart from some minor doubtful statements of an historical character, this section gives a good account of what is practicable under conditions in India; the importance of child leprosy, on which the author has written much, is stressed, as well as the segregation of infective cases, either in agricultural colonies, or if this is impossible because of lack of funds, in villages of their own. Because of the completeness of the clinical and treatment sections the work will be of practical value to leprologists everywhere.

## 1244 Atlas of Histopathology of the Skin

G. H. Percival, A. Murray Drennan & T. C. Dodds. Edinburgh, E. & S. Livingstone, Ltd., 1947. viii + 494 pages; 376 photomicrographs in colour. 24 x 20 cm. £3 15s. [£3.75]

(i) Terminology; (ii) normal histology; (iii) dystrophy and allied conditions; (iv) inflammation; (v) urticaria; (vi) lupus erythematosus; (vii) psoriasis; (viii) pityriasis rosea; (ix) lichen ruber; (x) pityriasis rubra pilaris; (xi) eczema; (xii) cheilopompholyx; (xiii) primary vesiculobullous eruptions of internal toxic origin; (xiv) primary vesiculo-bullous eruptions of external origin; (xv) pustular eruptions; (xvi) tinea; (xvii) rosacea and rhinophyma; (xviii) granuloma pyogenicum; (xix) traumatic injuries and the effects of stress; (xx) the reticuloses; (xxi) granulomatous conditions; (xxii) the naevi; (xxiii) cysts; (xxiv) tumours. Index.

The first reaction on turning over the pages of this new book is that the text is exceedingly brief for one so richly illustrated with coloured reproductions. However, on reading the preface one finds that the authors have, very fairly, already advised the student—and the reviewer—that the book purports to be an atlas and not a textbook of histopathology of the skin, and that their objective is "to portray in pictorial form the microscopical changes found in the more common diseases of the skin", the text being "severely limited just to what seemed necessary to explain briefly the processes illustrated".

The authors have certainly adhered rigidly to their intention in the greater part of the book. Exclusive of the descriptive notes beneath the illustrations, the text devoted to the subjects covered in the first 100 pages is written in about 450 lines, of which 52 are given to the Introduction, 50 to Terminology and 20 to Normal Histology, the remaining 325 being spared for the descriptions of "Dystrophy and allied conditions", "Inflammation", "Urticaria", "Lupus erythematosus", "Psoriasis", "Pityriasis rosea", "Lichen ruber" and "Pityriasis rubra pilaris". On reflection one cannot help but think that this is far too austere a use of words, particularly when the authors consider that the subject "Eczema" merits the relatively extravagant use of 320 lines.

The study of pathology of the skin is, like that of other diseases, by no means so simple that one can acquire sufficient knowledge by illustrations alone, and brief descriptions may not only be of little use but also prove very misleading. Of these there are many examples in the book, of which one may cite: "Sarcoid—the histological picture in the various clinical types of sarcoid is essentially that of a tuberculous process. The infiltration is circumscribed, it is deeply situated in the dermis and caseation is absent." Except for the last feature, most would disagree, for surely the picture differs considerably from the typical tuberculous reaction and "the infiltration", whatever that term denotes, is not usually situated deeply in the corium.

It is frequently argued that photomicrographs give a more accurate portrayal of a section than a drawing, an opinion with which the reviewer does not concur, for no matter how critical is the focusing, one must of necessity incorporate in the picture much that is above and below the plane of focus and which must therefore appear blurred, a factor which one eliminates on visual microscopical examination by frequent use of the fine-adjustment screw. It is for this reason that illustrations of cellular changes in the corium, as for example those found in chronic granuloma, prove of little value.

If only the authors could be persuaded to give rein to their extensive and valuable knowledge of the subject by enlarging the text and improving some of the deficiencies of illustration, the literature of this subject would indeed be considerably enriched.

## 1245 Skin Manifestations of Internal Disorders (Dermadromes)

Kurt Wiener. London, Henry Kimpton, 1947. 690 pages; 386 text-illustrations; 6 colour plates. 25 x 18 cm. £3 3s. [£3.15]

(i) The dermadromes of systemic infections; (ii-viii) systemic infections; (ix) helminthic diseases; (x) tuberculosis; (xi) dermatoses with claimed but still controversial tuberculous etiology; (xii) leprosy; (xiii) dermadromes of intoxications; (xiv) disorders of the circulation; (xv) diseases of the kidneys; (xvi-xx) disorders of the endocrine glands; (xxi) puberty; (xxii) menstruation; (xxiii) pregnancy; (xxiv) childbirth and puerperium. The skin in the newborn; (xxv) menopause; (xxvi) miscellaneous dermatoses with endocrine background; (xxvii) ageing; (xxviii-xxx) metabolic disorders; (xxxii-xxxiv) disorders of the blood and blood-forming organs; (xxxv) dermadromes of internal cancer; (xxxvi-xxxix) disorders of the nervous system; (xl) psychoses and psychodermatoses; (xli) disorders of the gastrointestinal tract; (xlii) diseases of the liver and pancreas; (xliii) disorders of the respiratory tract. Index.

A considerable proportion of the medical books published cover almost the same ground as others which are in current use. It is a refreshing change to find a book which deals with an unacknowledged aspect of medicine. The subject is treated broadly and in detail and all borderland topics are included.

The first 12 chapters are devoted to systemic infections and infestations. They include an account of the acute specific fevers with detailed descriptions of their exanthematous manifestations. Much of this material comes within the realm of a physician

rather than a dermatologist. The section entitled Dermatoses with Claimed but still Controversial Tuberculous Etiology contains a strange mixture: erythema nodosum, granuloma annulare, sarcoid, lupus erythematosus, and others. The etiology of these various disorders is discussed fairly.

Dermatitis medicamentosa is then discussed fully and includes an account of "atypical lichen planus" due to mepacrine (atabrine). This is followed by disorders of the circulation and of the kidneys. One of the illustrations suggests a confusion between Schamberg's disease and stasis dermatosis.

The most interesting part of the book is contained in the 15 chapters on endocrine and metabolic disorders. A brief description of each disorder is followed by a full account of its "dermadromes." The author's judgement seems to be faulty in suggesting estimations of the basal metabolic rate in all cases of vitiligo because this condition occurs in 10% of cases of thyrotoxicosis. A long list of dermatoses is given in which evidence has been produced for relationship to ovarian dysfunction, especially in individual cases, but the wise statement is made that "no dermatosis has been described which by its morphological picture alone would invariably permit the diagnosis of an ovarian dysfunction or disease." The section on puberty contains a particularly good and fair discussion of the part played by the gonads in *acne vulgaris*. The account of the dermatoses connected with menstruation, pregnancy, the puerperium, and the menopause abounds with information which is of great importance and which is by no means widely known. Under the heading "diabetes" Urbach's work on skin sugar and on "cutaneous glycoliposthia" ("dermal" would have been better) is described. The account of the vitamin deficiencies is orthodox. Among the conditions for which treatment with vitamin D may be given, *lupus vulgaris* is not mentioned.

The chapter on ageing includes a chronological account of the onset of wrinkles in the various areas of the skin. It is stated that the first wrinkles appear on the forehead and lower lids at the age of twenty-five.

As in all American works, the reticulososes are called "lymphoblastomas". The skin manifestations of leukaemia are divided into specific and non-specific. Following the chapters on the blood there are accounts of skin in internal cancer and in disorders of the nervous system.

The chapter entitled Psychoses and Psychodermatoses is the weakest in the book. It is interesting as far as it goes but is quite inadequate. The surprising statements, "Purely psychogenic urticaria is rare" and "purely psychogenic pruritus is rare", give a clue to the author's scepticism of the importance of psychogenic factors except as trigger mechanisms.

The final chapters deal with digestive and respiratory disorders. They are followed by seven tables, the first of which summarizes much useful information about the acute exanthemata. The second deals with diffuse pigmentations, the third with diffuse yellow pigmentations, the fourth with hypertrichosis, the fifth (an excellent and unusual presentation) with the skin in relation to age, the sixth with haemorrhagic diseases, and the last with pruritus. These tables are carefully compiled and make a valuable addition to the book. Unfortunately psychotherapy is not specifically mentioned in the list of ten treatments for pruritus. The index occupies 14½ pages, but could profitably be extended.

This is a very valuable reference book for dermatologists and probably also for the general physician. There are 3110 references, a considerable proportion of which pertain to the German literature. These references, in which there are a few misprints, are in the form of footnotes; at least one of the small numbers in the text is misplaced. The method of setting out the references seems to follow no system; in most of them the year follows the volume and page number, but in some it precedes them; in some the title of the paper is given in its original language and in some it is translated into English. There are a few surprising omissions, e.g., the books by Broster and his colleagues in the section on adrenal tumours, by Stannus on avitaminosis A, and Kuno in the section on sweating (though reference is made elsewhere to his work). Most of the 386 black-and-white illustrations are excellent but a few (e.g., fig. 17) are poor; some of the coloured plates are valueless. An immense amount of work has gone into the writing of this book and the publishers have produced it admirably.

E. Lipman Cohen

## ENDOCRINOLOGY

### 1246 Endocrine Function of the Hypophysis

Harry B. Friedgood. New York, Oxford University Press; London, Geoffrey Cumberlege, 1946. iv + 240 pages; 36 figures. 24 × 16 cm. £1 5s. [£1.25]

This book is reprinted from the Oxford Loose-Leaf Medicine and its presentation stands quite well alone, although it is not comprehensive. The first half of the book, on embryology and physiology, is not as good as the clinical sections, although great pains have been taken to give detailed references for many of the statements.

There is a slight confusion in the references to the cytology of the pars anterior (Tilney, 1938; Bucy, 1932) and the statement that the "cortical zone consists essentially of basophil cells" is quite contrary to the findings in man or to the original extraction of growth hormone from the bovine cortical rim of the anterior pituitary of cattle with its high eosinophil content. Of man, A. T. Rasmussen states quite clearly<sup>1</sup>, and it is also the experience of the pathological department of the London Hospital, that:

Histologically even more unreliability existed because of the habit of diagnosing the entire gland by general inspection of a single section, which too frequently was near the mid-sagittal plane. In the human hypophysis the distribution of the different types of cells is so irregular that nothing short of several horizontal sections suffice.

The acidophils tend to concentrate in a large area located somewhat posteriorly in each lateral half of the anterior lobe, leaving an area near the mid-sagittal plane and an anterior and a marginal zone where the acidophils are less numerous and hence richer in chromophobes and basophils.

A good deal of evidence is produced in favour of the basophil-cell origin of follicle-stimulating gonadotrophins, but it is also pointed out that luteinizing hormone is secreted by acidophil cells, which is not generally appreciated. The pathological physiology of exophthalmos is well dealt with and the long pages of closely printed matter are happily relieved in this section by excellent illustrations. The section on the complicated physiology and pathology of growth is excellent, with a very full bibliography. This section is followed by a sound clinical one on gigantism and acromegaly. The statement that "the growth of the hair on the head is remarkably thick" might be more qualified and is certainly not true of women, in whom it often falls out, as in primary virilism. The polyuria of acromegaly is well described but no reference is made to the opposite condition of diabetes tenuifluus, due to excessive secretion of pitressin, which may be present in some phases of acromegaly and is then associated with oliguria and excessive perspiration.

Attention is drawn to the fact that the epiphyses of giants "remain ununited many years beyond the period of normal ossification." This fact, not generally appreciated or known, does not refer to the tall eunuchoids, but to gigantism associated with an eosinophil adenoma or hyperplasia and must be ascribed (although this is not stated in the book) to the fact that hypogonadism is an accompaniment of the disorder. The statement is by no means true of all giants, and closure of the epiphyses may even be relatively premature, the great height being due to excessive secretion of growth hormone in childhood and early adolescence.

In summary, this is a good book, with full information on many aspects of a very involved subject, and deserves a place in the library of every scientific endocrinologist.

S. L. Simpson

<sup>1</sup> *The pituitary gland* (Proceedings of the Association for Research in Nervous and Mental Disease, December 1936), Baltimore, 1938.

### 1247 The Glands of Destiny: a Study of the Personality

Ivo Geikie-Cobb. Third Edition. London, William Heinemann Medical Books, Ltd., 1947. xii + 258 pages; illustrations. 22 × 14 cm. 15s. [£0.75]

Part I. (i) Introduction; (ii) the ductless glands and their secretions; (iii) the thyroid gland; (iv) the parathyroid glands; (v) the pituitary gland; (vi) the adrenal glands; (vii) the sexual secretions of the male; (viii) the female sex glands and their secretions; (ix) the internal secretions of digestion; (x) the pineal gland; (xi) the thymus gland; (xii) the internal secretions and the nervous system. Part II. (i) Personality and the internal secretions; (ii) the internal secretions in everyday life; (iii) racial characteristics and endocrine influences; (iv) from infancy to old age; (v) civilisation and warfare; (vi) on giants; (vii) on dwarfs; (viii) the present position of organotherapy; (ix) personalities; (x) the summing-up. Epilogue. Glossary. Bibliography. Index.

The sub-title of this book is "A Study of the Personality" and in this field it achieves a measure of success and historical interest. It is quite obvious that the writer is a man of culture and historical knowledge and a keen and thoughtful observer. Nevertheless the attempt to link his observations on personality with modern endocrinology, or even ancient endocrinology, is very weak and very often completely beyond any known facts. There is also a good deal of muddled and erroneous conjecture.

Of Henry VIII we read that "the anterior pituitary was probably somewhat countered by the posterior, otherwise the artistic element would not have been so marked"; of Queen Elizabeth, "the needs of a queen had called forth those glands which help to fight and to govern"; of James I, "his features and character point to a post-pituitary-thyroid dominant type"; of Charles I, "a little less of the posterior-pituitary and a stronger, better balanced, more masculine man might have resulted." All this may be very intriguing to the lay reader but to a scientific endocrinologist it is largely nonsense. This does not mean that the endocrine glands do not contribute to personality or that diseases of them may not seriously affect personality. A scientific treatise on this subject is yet awaited and maybe it is better to wait another decade before attempting it.

In the first section of the book, dealing with the function of the separate endocrine glands, there are innumerable mistakes. Thus a mongol, "like a cretin", is said to have "a puffy mis-shapen body with dry skin, subnormal temperature and slow pulse". Parathyroid deficiency is attributed to alimentary poisoning and the obsolete guanidine theory resuscitated. Pituitary feeding by mouth for obesity is advocated, whereas all scientific evidence fails to substantiate any such claims. "Anyone who can fall asleep at will would probably benefit from a stimulant to the pituitary gland." "Hypofunction of the adrenal medulla may exist as a disease entity, hypoadrenia." "The logical opposites of acromegals are the short swarthy goat-legged achondroplastics."

Although nothing can really compensate for such errors in a book dealing with endocrines there are interesting historical chapters on giants and dwarfs with case-histories and quotations. On the subject of glands and personality, the author unfortunately quotes from another book which has no greater scientific basis for many of its statements than his own. If the preface made clear that the book was for lay readers and that it had no scientific pretensions, it would serve the purpose of amusing and interesting without doing any great harm.

S. L. Simpson

## GERONTOLOGY

### 1248. Old Age: its Compensations and Rewards

A. L. Vischer. London, George Allen and Unwin Ltd., 1947. 200 pages; 9 illustrations. 22 x 14 cm. 12s. 6d. [£0.625]

(i) Senescence as a bodily and mental process; (ii) the duration of life; (iii) society and the individual: their attitude toward old age. Bibliography.

This book is an essay on the psychological and social aspects of old age written by one well qualified to do so in virtue of his twenty years' experience as physician to the Old People's Home of the city of Basle. The author is essentially a humanist, as is frequently displayed in his treatment of the physiological and pathological problems of senescence. His description of the gross changes in old age is excellent, but his explanations of them are such as must be regarded as unsatisfactory both by the scientist and the philosopher. Such statements as "life is gradual dying" and "ageing is a conflict between the nobler elements . . . and the simpler elements", though possessing attractions as artistic symbolisms, must remain unhelpful half truths.

Vischer shares the views of Bastai and Dogliotti that the actual cause of old age is an insoluble problem which is best left to the philosopher. It is to be hoped that the scientist of today approaching this problem of great interest and even greater social importance will not accept such an attitude.

In the second part of the book the author is dealing with matters of which he has very great knowledge. His main theme is that with successful adaptation of the individual and of society old age can be and often has been a phase of achievement which in its own way need not be inferior to or less happy than youth. His failure to draw a sharp line between mere chronological age

and physiological age weakens his position. He makes great play of the fact that a great painter given fifty years to develop his art may in the end produce finer pictures than in the beginning. This, of course, is a verifiable fact, but it does not dispose of the difficulty that a great many artists must have been prevented from their own further evolution by such conditions as cataract or paralysis agitans. Vischer's ideas concerning the compensations and rewards of old age presuppose as a minimum condition the preservation of the central nervous function. He forgets, however, that Montaigne said "en ay assez veu, qui ont eu la cervelle affoiblie avant l'estomach et les jambes".

This book has many merits. Where the author is calling upon his own experience concerning the care of old people, the nature of their needs and of the means of finding a place for them in society, he writes with great knowledge and understanding. In the latter half of the book, where he is reviewing the position of the aged in society throughout the centuries and the achievements of old people, he provides a veritable anthology of the best that both the past and present have to offer. His main contention that old age can and should be a stage of fulfilment rather than of frustration is well sustained by many examples from history and by the inclusion of some interesting reproductions which contrast the early and the late work of such masters as Titian, Tintoretto, Bernini and Renoir.

There must be but few who are interested in the problems of gerontology and geriatrics by whom this book will not be found both interesting and helpful.

F. A. E. Crew

## HEALTH THROUGH EXERCISE

### 1249. Physical Education

E. Harold Le Maistre. Melbourne, Oxford University Press; London, Humphrey Milford, 1945. xv + 310 pages; 67 figures. 22 x 14 cm. 11s. 6d. [£0.575]

(i) The history of physical education; (ii) the aim, objectives and principles of physical education; (iii) the scope and nature of physical education; (iv) safety in physical education; (v) the hygiene of physical education programmes; (vi) the relative value of physical education activities; (vii) anatomy and physiology; (viii) muscle location and action; (ix) tests and measurements in physical education; (x) posture; (xi) exercise and fatigue; (xii) tournaments and draws; (xiii) court, field and equipment specifications; (xiv) future trends in physical education. Selected bibliography for detailed references. Index.

This is a small compendium which is designed, in the words of the preface by Professor Harvey Sutton, "to bring before the teacher the scientific basis of the work, to set out a synopsis of our knowledge of structure and function of the human body, and also to furnish a wide variety of techniques for various sports and games in Australia." It thus deals with a wide variety of subjects ranging from a somewhat bare account of muscular attachments and actions, the physical activities of aboriginal Australians, the principles on which games shall be organized, physical tests and measurements and statistical methods, to the specifications for fields, courts and equipment, and a few data regarding gaseous exchanges in the body.

All topics are necessarily dealt with in a very abbreviated form, but as a work of reference it should be useful for the more administrative aspects of physical education. So far as the scientific aspects of human anatomy and physiology are concerned the very brevity of this book and the selection of its contents will tend to give teachers a superficial approach to a real understanding of the working of the body, and might indeed encourage the "cramming" of students, leaving their minds clogged with details of which they cannot appreciate the significance. It seems useless to enumerate the varieties of neuroglia, while the references to pH of the blood and to blood-buffers may convey a false sense of understanding unless the reader re-reads the elements of physiological chemistry elsewhere. The brief statements made regarding reflexes assist little in an understanding of their significance for physical education. Even the accounts of muscular actions are singularly incomplete; in the analysis of fundamental actions, the arm alone is dealt with. Nor is there any attempt at the analysis of the movements involved in exercises or games.

Mr. Le Maistre's book can be recommended as a convenient reference work in regard to simple details for those whose knowledge is already much wider than that presented by this book.

## MEDICAL HISTORY

### 1250 Magic and Healing

C. J. S. Thompson. London, Rider & Company [1947].  
176 pages; 20 illustrations. 22 x 14 cm. 15s. [£0.75]

(i) Magic and healing—early beliefs in the origin of disease; (ii) healing by incantation; (iii) healing and astrology; (iv) transplantation of disease; (v) healing by sympathy; (vi) healing by touch; (vii) healing in ancient Britain; (viii) Anglo-Saxon her; (ix) the healing art in ancient Britain; (x) the healing doctrine of signatures; (xi) the healing of plants; (xii) the healing of herbs; (xiii) plants of the devil; (xiv) herbs and plants dedicated to saints; (xv) plants and drugs used by sorcerers; (xvi) remedies of animal origin employed by the Anglo-Saxons; (xvii) precious and rare stones employed in healing; (xviii) man's body and its use in healing; (xix) magical girdles used in healing; (xx) magical and medicinal rings of healing; (xxi) magical stones of healing; (xxii) horns of healing; (xxiii) miraculous beds of healing; (xxiv) colours and numbers and their influence on healing; (xxv) toothache and its cure in antiquity; (xxvi) the psychological effect of magic in healing.

The author of this book, Dr. C. J. S. Thompson, who died in 1942, was an acknowledged authority on primitive medicine and on the art of the alchemist and the apothecary. That he loved to probe the mystery surrounding those subjects is evident from the fact that the word "Mystery" is included in the title of twelve of his previous works—*The Mystery of Poison*, of *Pharmacy*, of *Perfume*, or of *Astrology* and of *Apparitions* alike intrigued him and guided his pen to produce those fascinating and interesting studies.

The present posthumous work was left unfinished by the author, but it has been prepared for the press by his son and daughter, who are to be congratulated on the successful accomplishment of a difficult task. The only criticism, which many readers will share with the reviewer, is that this little work is overweighted with information, so that each page demands a serious study which rather detracts from the enjoyment of the reading. This difficulty is immensely increased by the absence of an index. For a work of this nature, an index is essential, and it is hoped that this defect may be remedied in future editions. The material is classified in 27 chapters. From *Early Beliefs regarding Disease*, we pass to *Healing by Incantation and by Touch*, to *Plants of the Devil and Plants of the Saints*, to *Magical Girdles*, *Medicinal Rings*, and *Miraculous Beds*, the *Doctrine of Signatures*, and the *Influence of Colours and Numbers*. The subject of medical folklore is immense, but its literature is relatively scanty. This new work is therefore to be accorded a welcome, a welcome somewhat saddened by the reflection that it is Dr. Thompson's last book. The illustrations are unusual and well chosen, but one misses a bibliography almost as much as an index.

Douglas Guthrie

### 1251 Joseph Lister : Father of Modern Surgery

Rhoda Truax. London, George G. Harrap & Co., Ltd., 1947.  
270 pages; 10 illustrations. 20 x 14 cm. 10s. 6d.  
[£0.525]

(i) The godless college; (ii) bachelor of medicine; (iii) the formidable; (iv) the killer in Glasgow; (v) the tragic Hungarian; (vi) living ferments; (vii) the killer revealed; (viii) test cases; (ix) presenting the evidence; (x) the discredited ligature; (xi) professor of surgery; (xii) innovations; (xiii) the vivisection controversy; (xiv) bitter opposition; (xv) the decision; (xvi) the centre of resistance; (xvii) storming the citadel; (xviii) the turning-point; (xix) antiseptics and asepsis; (xx) the long honeymoon; (xxi) Joseph, Baron Lister; (xxii) another Herakles.

This can scarcely be regarded as a new book. It is, indeed, the British edition of a biography which was first published in the USA several years ago. Nevertheless, as Lord Horder remarks in his illuminating foreword, "... we may surely welcome an edition of Rhoda Truax's biography of Joseph Lister in the country that boasts his birth and his life's work."

One may find it hard to realize that Lord Lister died as recently as 1912, and that only 82 years have passed since he first introduced the antiseptic method which was destined so soon to revolutionize the whole practice of surgery. The story of Lister's early life and training, of his adaptation of Pasteur's discovery of what was called "the germ theory" to the needs of surgery, of his struggle for the acceptance of his views, and of his ultimate complete success—all form a fascinating story and a noble theme for the biographer. Although there have been several biographies of Lister since the first authoritative work by his nephew Sir Richman Godlee appeared in 1917, there is still room and demand for a

short popular account, designed for the non-medical as well as for the medical reader. The work under discussion is a treatise of this nature, following conventional lines and portraying the old familiar facts, accurately and attractively, and all within the compass of 270 pages. It is a most interesting and readable description of the achievement of one of the greatest figures in the long history of medicine, who, by his introduction of the antiseptic method, earned so well the title of Father of Modern Surgery. The illustrations, rather poor, and bunched together in the second chapter, are a disappointing feature of the book, and there is a tendency to dramatize the facts and to introduce imaginary conversations to an extent less favoured on this side of the Atlantic than in America. There is, however, a useful index and a bibliography.

Douglas Guthrie

## MEDICINE AND LIFE

### 1252 The Occasion Fleeting

Hugh Barber. London, H. K. Lewis & Co. Ltd., 1947.  
viii + 199 pages. 22 x 14 cm. 15s. [£0.75]

(i) The pre-clinical years; (ii) the clinical years in a medical school; (iii) the provincial hospital years; (iv) medicine and morbid anatomy; (v) clinical acumen; (vi) the history and the signs; (vii) the consultant and the specialist; (viii) the spirit of the family doctor; (ix) the relatives and friends; (x) the art of the geriatrician; (xi) psychosomatic medicine; (xii) medical examination in the absence of symptoms; (xiii) the beginnings of disease; (xiv) medicinal remedies; (xv) pathognomy at the bedside; (xvi) doctors' dilemmas; (xvii) alcohol in its place. Bibliography.

This is a collection of essays, largely reminiscent in character, embodying the clinical wisdom acquired by the author during a long medical career of nearly half a century. The title will be known to all medical men, perhaps not to so many laymen, who may also read the book with pleasure and profit. It is a quotation from the first aphorism of Hippocrates,  $\delta \delta \epsilon \kappa \alpha \rho \rho \delta \varsigma \delta \epsilon \varsigma$ , and sets the tone for the whole work, which abounds in aphorisms, some original, many quoted. As examples of the former we may cite: "in diagnosis and treatment he gets the best results who has a receptive countenance"; "one generation is looking for a sign which may be discredited by the next, but clinical histories have a way of repeating themselves and live"; "right character, developed in childhood, is the best insurance against avoidable disease"; "examination passing is partly a necessary evil and partly good fun". Some of these aphorisms occur more than once in different essays, but criticism on this score is disarmed by a quotation from *The Autocrat of the Breakfast-table*: "He must be a poor creature that does not often repeat himself". Oliver Wendell Holmes, to judge by the frequency with which he is quoted, must be one of Dr. Barber's favourite authors: others are Laurence Sterne, Samuel Johnson, Robert Louis Stevenson, Lewis Carroll, Rudyard Kipling, and among medical writers Sir William Withey Gull, Sir William Osler, Sir James Mackenzie and Wilfred Trotter. Inserted between the essays are short fables designed to point the moral of what has gone before. Like most attempts of this kind they are apt to be somewhat dull, and thus fail to achieve their purpose.

Dr. Barber has a wealth of anecdotes, which are indeed one of the most attractive elements in his book, but his concluding remark, "one could write an essay on that", falls through too constant repetition. We like particularly the story of the country practitioner who was thrown into a ditch from his motor bicycle and knocked unconscious. On coming to, he found a ring of people standing over him and heard a voice saying, "Well, there now, if it isn't our own dear Doctor, and we've sent for him to come and see himself". There is also the slightly "naughty" one about the young married woman who wished her doctor to attend at her confinement, but was emphatic that she could not ask him to call to fix up the date, because it was his invariable custom on entering the room to say, "Well! What have you been doing?"

If one can attempt to catch any general theme running through the various essays of this book it is a somewhat wistful eulogy of the old-fashioned "family doctor", a term that Dr. Barber prefers to general practitioner. While recognizing and acknowledging the advantages brought by recent advances in medical science, he repeatedly expresses the view that we have lost something too in the passing of the older methods and customs. ## Circulatory dysfunction

In 1928 Frey and Kraut demonstrated in the urine a substance they termed Kallikrein, which had a selective action on the peripheral circulation. This so-called "vasomotor hormone" produces vasodilatation of the peripheral blood vessels, with increased blood-flow, limb volume and surface temperature; but without any appreciable effect on blood-pressure.

Kallikrein may be expected to be beneficial in peripheral vascular disease associated with vasospasm (intermittent claudication, Raynaud's disease) and in other conditions characterised by faulty circulation (diabetic and arteriosclerotic gangrene, acrocyanosis, chilblains).

The hormone has been identified in the pancreas and Kallikrein is now issued (as oral solution and ampoules) under the name 'Padutin'.

gathers, as much by reading between the lines as from any direct statements, that Dr. Barber views with some apprehension the advent of a national health service. In the following passage he even allows a note of cynicism to creep in which is foreign to the general tone of the book: "There will be less room for individual worldly wisdom in a new world which may believe itself to be wise; although it may behave a young man to touch his cap to a superior officer". Nevertheless the evils of the financial basis of private practice are exposed in several passages; for instance, "... it would have been rather nice to have refused to price a particular service; and this is one of the privileges of the honorary staff to a hospital"; or again, "... it is probable that there is no other calling in which the conflict between the scientific side and the financial side is so acute as it is in medicine". An example of how financial considerations may complicate practice is given in the chapter on the art of the geriatrician: "a young doctor's first idea should be as to whether he can earn the money; by which I mean deserve it". In another connexion however the profit-motive is upheld: "In British medicine, of which we are justly proud, the consultant has relied economically upon the support of the family doctor. It has been an excellent stimulus." Moreover, in one of the longest passages of the book devoted to a single topic, Dr. Barber defends in no uncertain terms the buying and selling of practices, concluding with the triumphant parting shot: "If the new service shows shortcomings in some directions, as well it may, I only wish to state that it must not be claimed as a set-off, that the public have been saved from the indignity of being bought and sold like chattels, because for those members of the community whom it concerned the results were excellent".

One of Dr. Barber's chief interests apart from medicine is obviously cricket, for metaphors and analogies from the game occur constantly throughout his book, and he proudly claims the most distinguished player as a member of his own profession. There stand out from these pages not only a charm and urbanity of manner but also a kindly, tolerant spirit that we believe it is not altogether fanciful to attribute to Quaker influence: the author's grandfather was a Quaker and he himself was at a Quaker hall of residence while a student at Manchester. The quotation from William Penn's *Fruits of solitude*, at the head of the essay on the consultant and specialist, is also significant.

We can imagine no more appropriate gift for a retired "family doctor" or layman with a "medical background" than *The occasion fleeting*, and we hope the author will not take it amiss if we describe it as an ideal bedside book. If we have read his character aright, he will not do so.

Cyril C. Barnard

## 1253 The Doctor's Job

Carl Binger. London, George Allen & Unwin Ltd., 1947. 243 pages. 22 x 14 cm. 12s. 6d. [£0.625]

(i) Background and changes; (ii) specialties and specialists; (iii) the choice of physician, medical fees and etiquette; (iv) the relationship of doctor and patient; (v) medicine and psychoanalysis; (vi) psychiatry and medicine; (vii) some common psychiatric problems; (viii) psychosomatic medicine or mind and body relationships; (ix) stomach ulcer; (x) allergy, asthma and tuberculosis; (xi) high blood pressure; (xii) the cure and control of disease; (xiii) recent achievements and tasks ahead; (xiv) convalescence and chronic disease; (xv) the prevention of illness; (xvi) office practice, hospitals and outpatient departments; (xvii) socialized medicine or paying the piper; (xviii) past, present and future. Bibliography. Index.

It is a pleasure to review a book like this, written evidently by a man who has put into it not only his great learning and experience, but his heart. This is clearly shown by the conclusion announced by the author in his introduction: "Nothing a man has of scientific acumen, personal integrity and human understanding is too much to bring to this job." In one reader at least the book created not only an increased pride in his profession but a lingering doubt whether anyone but a superman is equal to this task.

Dr. Binger deals with every aspect of medical work and always with emphasis on its effects on the mind and body of the patient, who is continually in the picture. He shows what a complicated and costly business the prevention, diagnosis and treatment of disease have become. In spite of sympathetic references, the author comes to the conclusion that in a modern industrialized world the day of the general practitioner is past. His place is to be taken eventually by the trained internist working mainly in a hospital or centre with co-operation whenever necessary with

the specialists. The number of these in the USA is indeed formidable—no less than 26 varieties officially recognized. Dr. Binger has some very wise remarks on their limitations as well as their virtues, and on the best ways of using them.

A particularly noticeable feature of the book is its insistence on the interaction of mind and body. Dr. Binger says, "The approximation of psychology and medicine is one of the most important steps, as yet perhaps not fully appreciated, which modern medicine has taken." His chapter on the psychiatrist, while cleverly dispelling some of the "mystery-man" atmosphere which has grown around him, is absorbing and to me convincing. Another of Dr. Binger's dicta is almost a summary of his intention in writing this book: "It is almost as important to know what kind of a patient has the disease as what kind of disease the patient has."

Tempting as it is to dwell on each chapter of the book I must resist it and come to the section which deals with the crucial question of how this complicated and expensive modern medicine can be brought within the reach of the ordinary citizen—a problem which is exercising the minds of politicians as well as doctors all over the world. Dr. Binger points out that even in the USA, the world exemplar of private initiative and voluntary effort, the socialization of medicine is making great strides. "At least three-quarters of the total number of hospital beds in the United States are paid for out of public funds," he states, and he evidently believes that this tendency will extend to other forms of practice. He speaks very sympathetically of the many interesting experiments in voluntary prepaid medical insurance and group practice but regards them as merely touching the fringe of the problem. A criticism I must offer on this part of the book is that Dr. Binger does not seem sufficiently to appreciate the potential dangers to the best traditions of our profession, and to the public, if and when the State becomes the chief paymaster, instead of the patient.

This fine book is one that every doctor and medical student would profit by, and it can be just as cordially recommended to the intelligent layman, for the thought and hard work that have gone to its making are concealed by the ease and lucidity of its style.

Alfred Cox

## 1254 János, the Story of a Doctor

John Plesch. London, Victor Gollancz Ltd., 1947. 579 pages; 37 illustrations. 20 x 13 cm. 18s. [£0.9]

Part I. Science, politics and personalities. Part II. The theatre, art, music and England. Appendix: a doctor's dialogues. Index.

Although the subtitle of this book is *The Story of a Doctor*, it seems more important that it is the story of a highly intelligent and versatile man: his life, his opinions and his anecdotes. As the first has been exceptionally rich and varied, the second are sound and freshly stated, and the last are harvested from intimacy with many of the great ones of Europe (among them Einstein, Kreisler, Reinhardt), it is full of interest.

Like too many autobiographies it is almost formless, resembling a life-time notebook arranged loosely into sections and into some chronological order. The writing is diffuse and without style, although this no doubt is partly because the book, as we have it, is a translation—from what language, curiously enough, the publishers do not tell us. It would be hard even to guess the language of the original, since according to the author's own account he has at different periods of his life used Turkish, Hungarian, German, Slovakian and "quite a smattering of Roumanian." It is hardly necessary to say that Dr. Plesch grew up in the polyglot, patriarchal atmosphere of the Austro-Hungarian Monarchy, where he learnt not only his languages, but acquired an early love for the arts, particularly music, and for medicine. "I grew up amongst doctors," he writes, "and from my earliest childhood I never had any other idea but to become a doctor myself." Yet for some time he seems to have faltered in his choice of profession, until the unnerving privilege of once conducting the crack band (usual conductor one Franz Lehár) of the austro-hungarian army, after which he finally renounced music in favour of medicine. Because the terms in Hungarian universities started and ended at different times from those in the rest of Europe, during the long summer vacations he was able to go to the great medical centres of Austria, Germany and Italy—"to any place where some great man was at work whose reputation attracted me."

He was in Berlin five years before Virchow's death, made his acquaintance and watched him dissect. After Hitler's rise to power Plesch, with his wife and three children, came to England, where he requalified and settled.

The author's own character and versatility, as well as his exceptional opportunities, must have helped to form the extraordinary galaxy of friendships of which the anecdotes adorn this book. The multitude of accounts of the notable or notorious of Europe between the two world wars is almost bewildering and it is often difficult to disentangle authentic personal experience from hearsay.

In the search to discover a satisfactory explanation of the purpose of life, Dr. Plesch accepts Goethe's motto, "that the practical solution is that life is there to be lived." He employed this motto not only in his advice to some of his patients, but lived up to it fully himself. It is a pity that occasionally his words (or those of the translator?) give the impression that the author is too conscious of his achievements, which left the reviewer sometimes with an embarrassed sensation. One tends, however, to forgive such slight indiscretions from a man who is not only knowledgeable in his profession but also a connoisseur of the values of civilized life. Apart from music, in which he showed talent in early youth, one of the illustrations in the book, a portrait of Einstein by the author, bears witness—to say the least—that he could paint, and he also had wide knowledge of the European stage, its actors and producers.

But not the least interesting are the author's opinions. Here he is often unorthodox, sometimes provocative, but never stupid. He advocates euthanasia, legalized abortion and tolerance of homosexuality. He says many wise and often original things about marriage, sex and about the doctor-patient relationship. He believes in moderation not only in the natural good things of life, but also in sport and in fresh air—a refreshing conception!

By opening the book at the index first, the reader may get a very good idea of the number of subjects treated—indeed, the author shows some immoderation in inclusion of subjects—but on all of them he displays humanism, humour, and open-minded intelligence.

G. Popják

## MICROSCOPY

### 1255 The Microscope and the Practical Principles of Observation

Theodore Stephanides. London, Faber & Faber Ltd., 1947. 160 pages; 20 illustrations. 22 x 14 cm. 10s. 6d. [£0.525]

Part I. Description of the microscope. (i) the stand; (ii) the optical system; (iii) choice of a microscope. Part II. Technique of microscopical observation. (iv) Illumination by transmitted light; (v) illumination by diffracted light or dark-ground illumination; (vi) binocular microscopes; (vii) methods for recording observations. Bibliography. Appendix. Index.

It is a curious fact that, perhaps more than any other instrument, the microscope has attracted the attention of those who in the best sense of the word are "amateurs". Such amateurs as Joseph Lister, Nelson and Barnard have made most important additions to microscopy. It is therefore not surprising to find that the writer of a book on the microscope is a Greek poet, who happens also to be a medical man.

Many books on microscopy describe fully the preparation and staining of animal and plant tissues and other objects for microscopical study but give little or no instruction as to their examination when actually upon the stage of the microscope. The present volume attempts to meet this want by giving a methodical survey of the technique of microscopical observation. Although it is written primarily from the medical angle the fundamental principles remain the same for all branches of microscopy. The first part of the book gives a systematic description of the microscope, with instructions on the choice of an instrument for particular purposes. Especially important is the insistence on a microscope with the standard Royal Microscopical Society's eyepiece, objective and substage diameters. The second part of the book deals with the technique of microscopical observation and here even those who are expert microscopists may discover points of interest, though they will by no means agree with every statement made. The causes of errors of interpretation due to bad centring of the optical system, bad

focusing of the condenser, bad regulation of the illuminating cone and bad correction for spherical aberration are well described. Information, not always easy to find in works on microscopy, is given on simple methods for determining the dimensions of an object, its shape and position. A bibliography of books giving more information on particular questions and an appendix with definitions of terms used in microscopy complete a useful if elementary book, which incidentally is written in impeccable English.

G. M. Findlay

## NERVOUS SYSTEM

### 1256 The Physical Background of Perception: Being The Waynflete Lectures Delivered in the College of St. Mary Magdalen, Oxford, in Hilary Term, 1946

E. D. Adrian. Oxford, Clarendon Press, 1947. 95 pages; 21 figures. 22 x 14 cm. 10s. [£0.5]

(i) The brain and the mind; (ii) the sense organs; (iii) motor and sensory areas of the brain; (iv) sight and hearing; (v) the electrical activity of the brain; (vi) recognition and mental events.

This little volume comprises the six Waynflete lectures delivered by Professor Adrian in Magdalen College, Oxford, in 1946. They are written for the enlightened layman, in that fluent style of his which by its simplicity of expression and modesty of exposition leads the reader to assume that to reveal all this was simple, and to synthesize the evidence revealed, easy. In point of fact the volume contains an account of Professor Adrian's recent original work on the excitable cerebral cortex, much of which has been published in *Brain* and the *Journal of Physiology* in the past few years.

He relates, within the limits of our knowledge, the representation of sensory function at the periphery and cerebral cortex and links the form of his representation to the biological importance of that function to the particular animal under review. From this he goes on to an account of the integration of the cerebral activity subserving the special senses, and to a discussion upon the meaning of the apparently spontaneous electrical rhythms which can be recorded from the brain. He ends with an essay on learning and memory.

Even those who are well versed in the electro-physiology of the central nervous system would do well to pause for a time and ponder the integration of evidence which this monograph represents. Those less directly concerned will be fascinated.

Denis Williams

### 1257 Anatomical Pattern as the Essential Basis of Sensory Discrimination: being the Forty-ninth Robert Boyle Lecture

W. E. Le Gros Clark. Oxford, Blackwell Scientific Publications [1947]. 16 pages. 22 x 14 cm. 1s. [£0.05]

Professor Le Gros Clark's Boyle lecture contains a combination of new information and speculation that makes it a very good shillingsworth for medical men, biologists, philosophers or any others interested in the problems of perception. He first summarizes some recent work on the arrangement of the nervous pathways connected with some of the sense organs. The earlier neurologists were content to describe the connexions between receptor and central nervous system and the pathways within the latter. The lines of two paths thus became very well known, and it was commonly supposed that anatomical investigation of these matters was now "complete". More recently neurologists, largely under the leadership of Le Gros Clark himself, have realized that the details of the arrangement of nerve fibres within the pathway and centres may be of the utmost importance. In some cases (e.g. the eye and ear), there is a point-to-point connexion between individual organs of the receptor surface and parts of the brain. But the distribution of the points relative to each other is not the same centrally and peripherally; there is an elaborate sorting on the way inwards. It is now becoming clear that the detailed arrangement of these connexions with the projection area is a matter of very great importance for the functioning of the sensory system. Here is a vast new field for

the anatomist to explore and this is a beautiful example of the truth that a study seems to be complete only when those who pursue it have not sufficient imagination to carry it further. The detailed study of the connexions of the sensory fields will claim the attention of anatomists and histologists for many years, especially as physiologists, using the clues provided by the anatomical studies, come to investigate the processes going on in these areas, and in turn suggest further studies of the distribution of the various elements.

At the end of his lecture, Le Gros Clark deals with a problem perhaps even more fascinating—how all these extremely specific connexions come to be made during development. Discarding the theory that growing nerve-fibres are directed by chemical influences, he suggests, following Weiss, that they are controlled by the ultra-structure of the matrix in which they grow. It might be added that recent workers, Beams and Marsh, have revived an older idea that electrical potential gradients influence the direction of growth and the whole question remains very open. As Le Gros Clark points out, the view that fibres grow along surfaces only pushes the problem back to a consideration of "the incredibly complicated ultra-structural pattern of the substratum in the early embryo". He points out that this, like all living patterns, is not a static anatomical unit, but is only "mirrored" in a continually-changing substratum, as is a reflexion in a running stream. The analogy is telling enough but it is startling to find him pursuing it in a final sentence to the question: "What is the living body a reflection of?" There is evidently material here for much discussion and thought, and the lecture is an excellent example of the stimulus that can be obtained by combining accurate observation with imaginative thinking.

J. Z. Young

## 1258 Diseases of the Basal Ganglia and Subthalamic Nuclei

D. Denny-Brown. New York, Oxford University Press; London, Geoffrey Cumberlege, 1946. [Reprinted from Oxford Loose-Leaf Medicine] iv + 116 pages; 4 illustrations. 24 x 16 cm. 12s. 6d. [£0.625]

This short monograph is Dr. Denny-Brown's contribution to the Oxford Loose-Leaf Medicine, republished separately. In it, the author has collected all the major contributions to our knowledge of this corner of neurology.

The sections in which he deals with the symptomatology of the major and minor syndromes caused by disorders of the basal ganglia are accurate, lucid and pleasant to read. The most important part of the monograph, however, is the introduction, in which the underlying anatomy and physiology of the disturbances are synthesized in a manner characteristic of the Sherringtonian school of neurology.

This chapter of a well-known medical textbook is in the first rank of descriptive medical writing.

## 1259 Sensory Mechanisms of the Retina with an Appendix on Electrorretinography

Ragnar Granit. London, Geoffrey Cumberlege, Oxford University Press, 1947. xxiii + 412 pages; 178 illustrations. 22 x 14 cm. £1 15s. [£1.75]

Section I. The electrical signs of excitation and inhibition in the retina and optic nerve. (i) The generation and inhibition of a rhythmic discharge in peripheral nerve. The nerve as a model sense organ; (ii) the electroretinogram and optic nerve response of some simple types of retina; (iii) the components of the vertebrate electroretinogram; (iv) the resting potential. Some further properties of the component potentials of the electroretinogram; (v) some characteristic properties of the discharge in isolated fibres of the optic nerve; (vi) the component potentials in relation to excitation and inhibition: summary of chapters i-v. Section II. The properties of rods and cones. Variations in area, intensity and duration of the stimulus in dark and light adaptation. "Flicker." (vii) The duplex nature of the retina as reflected in the electroretinogram; (viii) differentiation velocity as a function of the state of adaptation. The response to intermittent illumination; (ix) quantitative effects of variations in the strength of the stimulus; (x) the duplicity theory from the electrophysiological point of view. E- and I-retinas defined. Summary of chapters vii-x; (xi) interaction. Area, duration and intensity of the stimulus as interchangeable variables; (xii) some other forms of interaction. Synchronization. Section III. The properties of the photosensitive substances and the mechanism of excitation. (xiii) The absorption spectrum of visual purple and its photo-products. Visual violet; (xiv) chemical aspects of the problem. The significance of vitamin A; (xv) the regeneration of visual purple; (xvi) the photochemistry of visual purple. The spectral distribution of its sensitivity and the scotopic

luminosity curve; (xvii) light and dark adaptation. Section IV. Colour reception. (xviii) The nature and history of the problem; (xix) colour receptors in different types of retina; (xx) the dominator-modulator theory; (xxi) the composite nature of the photopic dominator system, the mammalian colour receptors; (xxii) the dominator-modulator theory and colour vision. Appendices. References. Author and subject indexes.

Newcomers to visual physiology are fortunate in that within recent months two modern contributors to this field of study—Dr. W. D. Wright and Professor Granit—have written monographs. Books of this kind not only lighten the reading of the novice, but also serve to underline and crystallize the views of the author upon vision as they stand today. Scientific papers do not always do this, because their appearance in print is often followed by maturer consideration, which may never achieve full weight except in a monograph of this kind.

Professor Granit's book is such a crystallization of views and, in addition, an extensive digest of the author's own experimental work. It is a book which everyone interested in visual physiology should make a point of reading.

The work is divided into four sections. Section III gives a concise account of the physiology and biochemistry of visual purple and related photosensitive substances. The section explains all the names used by other workers and discusses the interrelationships of the various pigments. There is one chapter devoted to light and dark adaptation and the review of the photochemical aspects as a whole is one of the best in the literature.

Section IV deals with colour reception and in Chapter 20 the author's dominator-modulator theory is fully stated. This theory, as many people will know, is based upon action potential records obtained, by the author's own microelectrode technique, from single (or at most a few only) optic nerve fibres. It is a pity that the details of this technique are so poorly described. One felt that one would like to know much more of the actual method itself. In the final chapter the author links his work with that of those who investigate vision from the subjective aspect and this part of the book, which might well have become extremely speculative, is quite in balance with the rest of the matter. Here the importance of the electrophysiological approach to colour vision is stressed. It has revealed, for example, the presence of the photopic dominator type of response from a single fibre; this fibre has a spectral sensitivity curve which covers most of the spectrum and could not be of much use to the animal for wavelength discrimination. The author recalls that v. Kries and several others of the older workers realized the partial independence of the sensations of colour and brightness—an independence which they found difficult to harmonize with the trichromatic theory and which is easily explained by assuming that the photopic dominator is a brightness receptor.

Sections I and II deal with the author's work on the electroretinogram and other electrical behaviour of the retina and optic nerve. Although these sections provide a clear account of the work, the general reader will not find them easy to read. Here the author stresses the importance of correlating the nerve discharge with the electroretinogram.

There are 34 pages of references.

## OTORHINOLARYNGOLOGY

### 1260 Lehrbuch der Hals-Nasen-Ohren- und Mundkrankheiten

Edited by A. Barraud, F. R. Nager, L. Rüedi, E. Schlittler & J.-P. Taillens. Basel, S. Karger, 1947. xii + 609 pages; 177 illustrations. 25 x 17 cm. Sw. fr. 60.

I. Allgemeiner Teil. (i) Allgemeine Untersuchungstechnik; (ii) spezielle Untersuchungsmethoden für Mundhöhle, Rachen, Nase, Kehlkopf und Ohr; Tracheo-Bronchoskopie und Ösophagoskopie; Röntgenuntersuchung, Diaphanoskopie. II. Spezieller Teil. (i) Die Erkrankungen der Mundhöhle; (ii) die Krankheiten des Rachens; (iii) die Erkrankungen der Speiseröhre; (iv) die Krankheiten der Nase und ihrer Nebenhöhlen; (v) die Krankheiten des Kehlkopfes; (vi) die Erkrankungen der Luftröhre und der Bronchien; (vii) Stimm- und Sprachstörungen; (viii) die Erkrankungen des Ohres; (ix) Innenohr und vegetatives Nervensystem; (x) Otoneurologie des Zentralnervensystems; (xi) die Vererbung in der Otolaryngologie. III. Die Bedeutung der Hals-Nasen-Ohrenheilkunde für die ärztliche Gutachterfähigkeit; Ohr und Schule; Hörapparate, soziale Fürsorge. (i) Hals-Nasen-Ohrenheilkunde und ärztliche Gutachterfähigkeit; (ii) Ohr und Schule (Schwerhörigenschule, Taubstummenanstalt); (iii) Hörapparate—soziale Fürsorge. IV. Rezeptsammlung. V. Sachregister. VI. Namenregister.

This swiss textbook must be welcomed as a notable modern treatise on the diseases of the mouth, throat, nose, larynx and ear. It is a first-rate textbook for students, and postgraduates and specialists too will find it a comprehensive work of reference. The importance of a background of general medicine is stressed throughout.

An excellent feature is an introduction on the taking of the case-history designed to disclose any condition which might give rise to ear, nose and throat symptoms. This is followed by a brief explanation of the meaning of the common ear, nose and throat symptoms and a clear outline of the special examinations; it seems unnecessary to show the Killian-Bruning endoscopes, while mentioning in the text that the distally illuminated tubes are extensively used.

The arrangement of subject-matter is excellent. The same plan is followed as far as possible in all diseases: etiology, pathology, diagnosis and treatment are discussed in turn. There are no descriptions of operations, since these are regarded as the province of specialists. The exceptions to this are very clear descriptions of laryngotomy and tracheotomy, and of intubation.

The *Mouth* is dealt with first; a feature here is the tabulation of the diseases due to hypovitaminosis and a description of the conditions due to poisoning with mercury, lead, gold, silver, arsenic and iodides.

The *Pharynx*: the tonsil and adenoid problem is discussed fully and very sound conclusions arrived at, which should be of great help to doctors. There is also a very good description of the various throat-affections consequent upon blood diseases.

The *Nose and Sinuses*: like all the rest, this section is full of highly practical advice. In the discussion on headache, extra-nasal causes are given as well as nasal, and the point made that if the application of cocaine to the middle turbinal diminishes the pain, the cause is probably in the nose or sinuses. Advice is given against the use of alum in the nose, as it has a specific toxic action on the olfactory nerve.

In dealing with epistaxis no mention is made of the recently-suggested ligation of the ethmoidal artery in uncontrolled cases. And there is no mention of calciferol in the treatment of lupus.

The *Larynx, Trachea and Bronchi*: all comprehensively dealt with; the diagrams of the cords and their paralyses are good. It is of interest to read that in 1.5% of thyroidectomies, paralysis of one recurrent nerve occurs, and that bilateral paralysis occurs during or after operation, "especially if one cord was paralyzed before operation by the thyroid swelling." The coloured plate of laryngeal diseases is not so good as others.

The *Ear*: this part has set a very high standard to any competitor. Not only are the descriptions of the anatomy and pathology admirable, but they are illustrated by many reproductions of microscopical appearances of sections of the temporal bone, of great value to the reader. Every complication of acute and chronic inflammation is described and explained; indeed, there is a wealth of practical information, both for student and expert.

Every aspect of deafness is considered. The section dealing with deaf-mutes is fully illustrated to show the method of teaching lip-reading, and concludes with advice on their treatment as human beings and the help that can be given them by clubs and social service.

Throughout the work, treatment by sulpha drugs and penicillin is advocated, but there is no mention of methods of administration nor of dosage, and even today dosage is not standardized.

This is one of the best textbooks, if not the best, of the present day on the diseases of the speciality; it contains a great store of information in a most readable form.

W. M. Mollison

of liver disease; (viii) infiltration of the liver and post-infiltrative fibrosis; (ix) parenchymatous hepatitis; (x) cholestasis; (xi) cholangitis; (xii) biliary ducts, and biliary diffuse hepatic fibrosis; (xiii) cholangiocarcinoma; (xiv) cancer of the liver; (xv) conclusions. Index.

Within the past ten to fifteen years certain facts in the pathology of the liver have assumed a major importance. These are: (i) the possibility of producing extensive and fatal hepatic necrosis in experimental animals by manipulation of the diet; (ii) the possibility of producing extreme fatty change in animals by similar means; (iii) that such fatty change may be a precedent incident in cirrhosis of the liver; (iv) that certain "lipotropic" substances will prevent or abolish such fatty infiltration. It is the endeavour of the author to bring together these various observations, and to unite them in a relatively-simple concordant theory of liver pathology.

His first postulate is that liver necrosis is essentially an ischaemia, due to swelling of liver cells and obliteration of the sinusoids; his next is that hepatic necrosis is essentially of two types, differing fundamentally: the one, a "massive necrosis" of irregular large areas of liver with no particular anatomical distribution (save that the left lobe is liable to suffer more than the right); and the other, a "zonal necrosis", i.e. an anatomically defined necrosis limited to lobules, affecting them all, but not confluent. This difference is pushed further into the chronic stage, or stage of partial recovery, so that the first lesion results in an irregularly scarred liver—"post necrotic scarring" (the nodular hyperplasia of other authors); and the second in a fibrosis destructive of lobular pattern—"diffuse hepatic fibrosis" (classical portal cirrhosis). These contentions are widely agreed, though the writer introduces a new terminology, but there is much that is new in the support of the argument by a large amount of experimental work, mainly, if not wholly, upon rats, which emphasizes with great clarity the distinction between the two pathological pictures. In this work Professor Himsworth was assisted by a pathological colleague, Dr. L. E. Glynn.

The results of this investigation show, broadly speaking, that the dietary deficiency which leads to massive liver necrosis is a lack of protein, and in particular the absence of the sulphur-containing amino-acids, methionine and cystine. It has frequently been observed that in acute necrosis of the liver the left lobe suffers more than the right and the ingenious explanation is put forward that as the right lobe receives principally blood from the small intestine, whereas the supply to the left lobe is largely admixed with blood from the splenic vein, it is to be expected that the former will receive amino-acids absorbed from the intestine in higher concentration, and thus suffer less when there is a specific deficiency of these in the diet. On the other hand, the lobular lesions which lead to a typical portal cirrhosis were found to be a sequel of gross and prolonged fatty infiltration of the liver; in the rats used for these experiments the fat content produced was between seven to fifteen times the normal, and this was maintained from 100 to 300 days, that is, for a period equivalent to about seven to twenty years of a man's lifetime. Such a condition is obviously an extreme one and it may legitimately be questioned how far such a result can be applied to explain the disease in man.

The experimental conditions producing this fatty change and subsequent fibrosis can also be shown to be dietetic, the condition being occasioned either by diets rich in fat, or by those deficient in "lipotropic" substances such as lecithine, choline, methionine and some others. In sum, the difference between these two forms of fibrosis and necrosis are: the massive form of the one and the lobular form of the other; the absence of notable fatty change in the one and its characteristic appearance in the other; the production of a fibrotic type of lesion, having the picture of nodular-type hyperplasia with large areas of regenerated liver in the one, and of portal cirrhosis, with an absence of recognizable liver lobules, in the other.

From this experimental and pathological study the author turns to human liver disease. It has long been known that fatty infiltration is a common feature of "alcoholic cirrhosis" but the exact relationship of the two conditions has been ill-understood. Professor Himsworth believes it to be a causal one, the liver cells, swollen by infiltrated fat, compressing the blood vessels and leading to a quiet disappearance of the liver parenchyma and an overgrowth of fibrous tissue, especially of the portal tracts. He further points out the high incidence of cirrhosis in certain coloured races in some parts of the world where alcohol is not apparently to blame and where dietary deficiency, especially

## PATHOLOGY

### 1261 Lectures on the Liver and its Diseases: Comprising the Lowell Lectures Delivered at Boston, Massachusetts, in March 1947

H. P. Himsworth. Oxford, Blackwell Scientific Publications, 1947. xiii + 204 pages; 58 figures. 23 x 15 cm. 18s. 6d. [£0.925]

(i) The types of liver injury and their structural consequences; (ii) the vascular factor in liver injury; (iii) nutritional factors in liver injury: experimental; (iv) nutritional factors in liver injury: human; (v) noxious factors causing liver injury; (vi) the syndromes of hepatic failure; (vii) the clinical classification

in the rather expensive protein substances we have considered, is widespread. This is often particularly marked in infancy and young adult life in the poorer native races, and a good case is made out for a dietetic cause for this fibrosis; likewise the incidence of primary hepatic cancer—something of a rarity in Western Europe, and a well-known complication of liver fibrosis with regenerative areas—is instanced to support the same argument. Alcoholic cirrhosis is explained on the ground of the effect of chronic gastritis on appetite and food-absorption, and the predilection of the chronic alcoholic for spending his money on drink rather than upon the lipotropic factors which are so good for him.

The argument we have sketched in its broad outline occupies about half the book and is of the greatest interest. It is not too easy to read and suffers from a certain amount of reiteration. The rest of the book is devoted to a less penetrating analysis of other diseases of the liver, with a sharp eye to the main thesis. Hepatitis, the effects and action of poisons, and the various manifestations of hepatic failure are analyzed. There is a strange statement under the heading which includes fatty infiltration that "the infiltrating material is confined to the parenchymal cells where it presumably is formed" which must not be taken too literally, and a dreadful heresy that amyloid disease comes into the class of "conditions in which the liver cells are distended by some substance which accumulates in their cytoplasm".

Professor Himsforth has written an extremely well-documented and stimulating book. He sagely remarks that "The progress of knowledge can be as effectively impeded by a misconceived hypothesis as by factual ignorance"; time will show what place in the Valhalla of medical theories awaits those put forward in his book. Be this as it may, clinicians and pathologists will be grateful for the material here assembled and appreciate the tenacious investigation which has led to these conclusions.

J. H. Dible

## 1262 Pathological Histology

Robertson F. Ogilvie. Third Edition. Edinburgh, E. & S. Livingstone Ltd., 1947. xii + 459 pages; 260 illustrations. 22 x 14 cm. £1 17s. 6d. [£1.875]

(i) Disturbances of nutrition; (ii) disturbances of the circulation; (iii) inflammation and repair; (iv) specific inflammations; (v) tumours; (vi) tumours (continued); (vii) circulatory system: blood vessels; (viii) circulatory system: heart; (ix) respiratory system; (x) alimentary system: stomach and intestines; (xi) alimentary system: liver and gall bladder; pancreas; (xii) urinary system; (xiii) reproductive system; (xiv) haemopoietic system; (xv) nervous system; (xvi) integumentary system; (xvii) locomotor system; (xviii) endocrine system. Index.

This book is now established as a reliable guide to the practical study of pathological histology. It contains 260 beautifully executed photomicrographs in colour of the histological changes accompanying all the more common disease processes. The colour rendering is faithful and the choice of magnification and fields has obviously been carried out by a teacher of this subject of wide experience. Each illustration is accompanied by an adequate legend and the text of the book contains commendably brief and lucid general descriptions of each process illustrated.

The book can be recommended as the best possible substitute for a demonstrator of pathology to the student who is working through his own collection of sections, and should be most valuable in these days when classes tend to be overcrowded and skilled demonstrators "in short supply".

G. Hadfield

## 1263 Pathology of Tumours

R. A. Willis. London, Butterworth & Co. (Publishers), Ltd., 1948. xxiii + 992 + 52 pages; 500 illustrations. 25 x 17 cm. £3 3s. [£3.15]

Part I. (i) Definition of tumour; (ii) classification and nomenclature; (iii) innocence and malignancy; (iv) experimental production of tumours; (v) statistical study of tumours; (vi) tumours in animals; (vii) the mode of origin of tumours; (viii) structure and growth of tumours; (ix) the direct spread of tumours; (x) metastasis; (xi) hypotheses as to the nature of neoplasia; (xii) recapitulation. Part II. (xiii) Epithelial tumours of the breast; (xiv) epithelial tumours of the skin; (xv) epidermoid carcinomas of the lips, mouth, pharynx and larynx; (xvi) tumours derived from the epithelium of the dental lamina; (xvii) epithelial tumours of the salivary glands; (xviii) epithelial tumours of the nasal and paranasal cavities; (xix) epithelial tumours of the trachea, bronchi and lung; (xx) carcinoma of the oesophagus; (xxi) carcinoma of the stomach; (xxii) epithelial tumours of the small intestine; (xxiii) carcinoma of the large intestine; (xxiv) carcinoma of the liver; (xxv) epithelial tumours of the biliary tract; (xxvi) epithelial tumours of the pancreas; (xxvii) adenoma

and carcinoma of the kidney parenchyma; (xxviii) epithelial tumours of the urinary passages; (xxix) epithelial and related tumours of the ovary; (xxx) carcinoma of the Fallopian tube; (xxxi) epithelial tumours of the uterus; (xxxii) epithelial tumours of the vagina and vulva; (xxxiii) epithelial and related tumours of the testis and epididymis; (xxxiv) carcinoma of the prostate; (xxxv) epidermoid carcinoma of the penis and scrotum; (xxxvi) epithelial tumours of the thyroid gland; (xxxvii) epithelial tumours of the thymus; (xxxviii) epithelial pituitary and parapituitary tumours; (xxxix) tumours of the adrenal cortex; (xl) tumours of the parathyroid glands; (xli) introduction to mesenchymal tumours: fibroblastic tumours and myxomas; (xlii) tumours of adipose tissue; (xliii) tumours of cartilage and bone; (xliv) tumours of synovial tissue; (xlv) angiomas: tumours and tumour-like overgrowths of vascular tissue; (xlvi) meningioma or arachnoid fibroblastoma; (xlvii) leiomyoma and leiomyosarcoma; (xlviii) rhabdomyoma, rhabdomyosarcoma, and rhabdomyoblastic mixed tumours; (xlix) tumours of lymphoid tissue; (l) plasmacytomas and myelomatosis; (li) other neoplasms of haemopoietic tissues; (lii) the glioma; (liii) papillary tumours of the choroid plexus; (liv) neurilemmoma and other tumours of nerve-sheaths; (lv) neuroblastoma and ganglioneuroma; (lvi) tumours of chromaffin tissues and of the carotid and aortic bodies; (lvii) neuro-ectodermal tumours of the retina and ciliary body; (lviii) the melanomata; (lix) chordoma; (lx) embryonic tumours of kidney and liver; and general comments on embryonic tumours; (lxi) the teratomata; (lxii) chorion-epithelioma.

The need for a new, comprehensive textbook on the pathology of tumours has been felt for a long time by workers in this particular field as well as by morbid anatomists in general. Without doubt, the *Pathology of tumours* by Professor R. A. Willis will go a long way towards meeting this need. Admirers of his former writings, especially of *The spread of tumours in the human body*, will know that his interest has for long been focussed on tumour pathology. In this book of over 1,000 pages, he brings the experience of years to bear upon our present knowledge of tumour problems. Thus we are presented with an extraordinarily able summary of other workers' opinions and findings, together with Professor Willis' own views, more often than not formed as a result of personal investigation and expressed in no uncertain terms. In consequence, it is hardly likely that all the views expressed will be accepted without reserve.

One-fifth of the book is devoted to general considerations and this includes a helpful and up-to-date chapter on the experimental production of tumours, a vast subject at this present time. The other four-fifths, i.e., the main part of the book, are concerned with the pathology of tumours in various organs, and describe systematically: (a) the epithelial tumours of the breast, skin, digestive and respiratory organs, genito-urinary system and ductless glands; (b) the tumours of mesenchymal tissues, skeletal, myeloid and nervous. The incidence according to site, age, sex, race and species is discussed, as well as causative factors, structure, growth, metastasis, etc. The short references to tumours in animals and the descriptions of personally-observed representative cases are useful. There is a final section on the melanomata, chordoma, embryonic tumours, teratomata and chorion-epithelioma. Not a few of these subjects, for example the epithelial tumours of the skin, the teratomata and testicular and ovarian tumours, have been the special interest of Professor Willis for many years. In all cases, a critical summary of the work of other authors is presented, and at the end of each chapter is a comprehensive bibliography, in which those papers which have been found to be particularly helpful and instructive are listed in large, heavy type, and the full title included. This original and selective method is much to be commended. "Whatever omissions I may be guilty of in my reference lists, I can at least claim that they comprise works which, with very few exceptions, I have personally consulted in the original". The illustrations, mostly photomicrographs and numbering 500, are all from personally studied material. The standard of reproduction is very high and the legends particularly valuable. The selection is, perhaps, a little arbitrary; for example, there are 15 photomicrographs of fibro-adenoma of the breast and none of Brenner tumour of the ovary.

Many of Professor Willis' views will command agreement from most pathologists. For instance, the chapters on epithelial tumours of the testis and ovary are excellent and summarize current opinions fairly and clearly. Other of his opinions are less easily accepted. He would dispense completely with the term "endothelioma" and would classify tumours of mesenchymal tissues which happen to possess surfaces, with other tumours of mesenchymal origin. He supports entirely the epidermal origin of the melanomata; his main objection to a neural origin "is that these lesions are, as already insisted, plainly of epidermal origin". This does not seem to be a very cogent argument. He regards Paget's disease of the nipple as a form of epidermal carcinoma in situ, contrary to the views of Muir and others.

This is a book which no pathologist can afford to be without. It is a mine of up-to-date information, is most readable and is a model of accuracy and good sense. In addition, it contains that element of provocation which stimulates the reader to further thought and reading.

Georgiana M. Bonser

## PSYCHOLOGICAL MEDICINE

### 1264 Child Psychology

Arthur T. Jersild. Third Edition. London, Staples Press Limited, 1947. xi + 623 pages; figures. 21 x 14 cm. £1 10s. [£1.5]

(i) Beginnings of behavior; (ii) some general characteristics of development; (iii) some aspects of living and learning in infancy and early childhood; (iv) motor development; (v) development of social behavior; (vi) development of social behavior (*continued*); (vii) feeling and emotion; (viii) feeling and emotion (*continued*); (ix) language development; (x) the growth of understanding; (xi) growth of understanding (*continued*); (xii) children's make-believe, dreams, and other imaginative activities; (xiii) children's ideals, morals, and religion; (xiv) children's interests; (xv) the growth and prediction of intelligence; (xvi) personality and problems of adjustment. Author index. Subject index.

There is a pressing need for a good textbook on child-psychology; and, within the limits that he has set himself, Professor Jersild's book may be warmly recommended as a sound and scientific review of the subject. The third edition has been largely re-written. It incorporates all the latest American work of any importance, and appends excellent bibliographies on the chief topics at the end of each chapter.

Professor Jersild's primary purpose is to present a clear picture of the development of the child's personality. He is interested more in the emotional, moral, and social aspects than in problems of intellectual growth. The chapter on intelligence is comparatively brief; and the book makes no attempt to discuss in any detail the nature and maturation of special intellectual capacities, as assessed by psychological or educational tests or studied by factorial procedures. These topics, however, have already been fairly well covered in previous publications. On the other hand, there is at the moment no other book which succeeds so well in summarizing what is known about the development of feelings, interests, and ideals.

Professor Jersild adheres to no single school of thought; and his treatment is at once critical and eclectic. His tabular summaries giving the results of questionnaires and other inquiries upon such topics as children's games, commoner modes of enjoyment, range of worldly knowledge, and the like, at successive years of life, are most informative; they serve admirably to remind the student how essential it is to check hypotheses by objective data. Unfortunately, most of the summaries relate to investigations carried out in the USA. Hence, the inferences drawn may not always apply to children on this side of the Atlantic. The very words used to describe the children's favourite games will be unfamiliar to many British readers. That, however, is almost unavoidable, since few researches of this type have been carried out on any extensive scale in Britain. It is to be hoped that this English issue of the book will stimulate British psychologists and research-workers to institute similar inquiries.

### 1265 The Shaping of Psychiatry by War

John Rawlings Rees. New York, W.W. Norton & Company, Inc., 1945. 158 pages. 21 x 14 cm. 10s. 6d. [£0.525]

(i) The frontiers extend; (ii) opportunities emerge; (iii) the way ahead. Appendix: The tasks of psychiatry. Index.

No one is better fitted than Dr. J. R. Rees to describe how British psychiatry adapted itself to the calls made upon it by war, since he was Consulting Psychiatrist to the British Army from 1939 to 1945 and was responsible for most of the organization of army psychiatry during this time.

In this book, which is in substance the Thomas Williams Salmon memorial lectures given by Dr. Rees to the New York Academy of Medicine, he gives a very clear explanation of how dullards in the Army tended to form a social-problem group until it was discovered that drafting them to the Pioneer Corps was both therapeutic for the men themselves and productive of effective units for the war effort. He tells us that war provides more opportunities for psychiatrists than for physicians, and that very

soon the man-power problem brought to the front the importance of selection. A Directorate of Personnel Selection was set up by the War Office under the Adjutant-General shortly after the Admiralty had started its own selection service for the Navy. The Royal Air Force, which had its flying crew selection at the start of the war, only later used selection methods for its ground staff.

For officer selection, which had previously been done by the "magic eye" technique, three group projection tests were developed which, with questionnaires and an intelligence test, formed the battery used for each candidate. Follow-up statistics showed the superiority of scientific techniques to the older methods in this type of selection also.

Dr. Rees says that morale can almost be defined as mental health and shows how low morale is associated with high sickness- and high delinquency-rates, including absence without leave. Nevertheless discipline cannot replace morale. He describes the value of films and radio talks in keeping up the spirits of soldiers long absent from home, and in discussing rehabilitation he shows how progress is resulting in a move away from the formal occupational therapy of recent times to individual care and welfare work and he instances what has been done for the blind, the partially sighted and the limbless.

He believes that the psychiatrist's work should be done not only in the out-patient department of a hospital but also in connexion with instability, social unrest, morale, and in advising modifications of working conditions, on welfare and on the use of leisure, on training and allocation, etc. In order that this can be done, procedures, tests and techniques will have to be worked out and adequate staffs provided, including psychologists, sociologists and statisticians. We are warned that malcontents and subversives will be called "communists" or worse unless we are able to demonstrate that they are men who have been unwisely handled and who are reacting like rebellious and difficult children. Dr. Rees also warns psychiatry against its internal difficulties, and its "old men," and says that it is too much dominated by clinical interests, by psychoses, and by local government.

The book is most stimulating and in these days of planning it is highly desirable that it should be read by all who may have responsibilities for organizing the future mental health services of the country. Quotations such as "Psychiatric thought must become part of the ordinary approach to his tasks of every worker in the field of health and human relations," and "Psychiatry must be planning in a strategic manner for the mental health of the future," indicate the breadth of the author's conception of the future of psychiatry. Just as Dr. Rees was one of the few who could have organized army psychiatry for the needs of war, so we shall have to rely on him to convince a wider public of the contribution which psychiatry can make to the health of the community in time of peace.

J. G. Hamilton

## PUBLIC HEALTH

### 1266 Handbook of Preventive Medicine (Air Ministry Publication 1269B)

Air Ministry. London, His Majesty's Stationery Office, 1946, reprinted 1947. vi + 213 pages; 42 illustrations. 23 x 15 cm. 7s. 6d. [£0.375]

(i) Personal hygiene; (ii) water; (iii) food and nutrition; (iv) environment; (v) conservancy; (vi) communicable diseases; (vii) disinfection and disinfection. Index.

A valuable and comprehensive survey of preventive medicine is contained within the 213 closely printed pages of this handbook published by the Air Ministry. The Royal Air Force have the deserved reputation of doing things well; their practice of hygiene is of high standard. One has been impressed not only in reading this book, but also from first-hand observation, by the ingenious practical ways devised by medical officers of the RAF in overcoming difficult problems of hygiene. Although, in conformity with service traditions, no names of authors are given, it is obvious from the pages of this handbook that the authorities responsible for it are masters of their job in theory and practice. One can detect that an effective "brains trust" has been busy, and apart from its own resources has had access to the best of current teaching. The hard experience gained through years of peace and combat, through scenes and conditions even more varied

than Greenland's icy mountains and India's coral strand, from the sub-stratosphere to the Libyan deserts, is reflected in these pages.

The excellent Chapter IV (Environment) contains sections on effects of heat and cold, hygiene and sanitation, heating of camps, lighting and ventilation, all of which are first-class. It is good that Bedford's charts on "effective comfort zones" have been reproduced. The illustrations are clear, but few readers, one fears, will study the many tables.

Minor points which the reviewer does not like so much include:

(i) The rather close type and the fact that it is difficult, with this style of binding, to read the end of the line on the left-hand page; this can be obviated to some extent by loosening the binding cord. (ii) Under the section of methods of dealing with head infestation it would be wise in a future edition to include methods using DDT and Gammexane, mentioned in a separate section, as well as the Lethane treatment prescribed. (iii) Not every authority would agree that for scabies it is "imperative" to have two treatments with benzyl benzoate. (iv) In the section on communicable diseases more direct statements regarding the source of infection in syphilis and gonorrhoea might be considered. (v) Most important of all, the subject of Health Education deserves a separate chapter. It is all important to gain the co-operation of every man and woman in the Forces, and a syllabus of talks, together with a description of modern methods of health education and the way of raising the ideas and ideals of service personnel, is very necessary. (vi) The chapter on personal hygiene might be enlarged and the instructions on tooth brushing extended to other aspects of personal hygiene. These are of the greatest importance to morale as well as to physical fitness.

At the price of three half-crowns this handbook is a marvel of cheapness, conciseness, and good teaching. Many public-health students, other than Service personnel, will gain the greatest benefit from its study.

J. L. Burn

## 1267 Recent Advances in Public Health

J. L. Burn. London, J. & A. Churchill Ltd., 1947. viii + 409 pages; 82 illustrations. 22 x 14 cm. £1 5s. [£1.25]

(i) Introductory. Public health and the individual: (ii) Public health nursing service; (iii) the care of mother and child; (iv) nursery care; (v) school health services; (vi) health education; (vii) mental health services; (viii) dental health services; (ix) medico-social services; (x) the handicapped child; (xi) the care of the family; (xii) welfare of the aged. Public health and the community: (xiii) Poverty and public health; (xiv) rehabilitation; (xv) health centres; (xvi) municipal food health services; (xvii) rural epidemiology; (xviii) airborne infections; (xix) diphtheria immunisation; (xx) methods of vaccination against smallpox; (xxi) tuberculosis; (xxii) venereal disease; (xxiii) scabies; (xxiv) verminous infestation; (xxv) municipal ambulance service; (xxvi) co-operation of voluntary and municipal agencies; (xxvii) international health relations. Public health and the environment: (xxviii) Smokeless air; (xxix) water purification; (xxx) swimming bath water; (xxxi) milk. High temperature short time method of pasteurisation; (xxxii) food substitutes; (xxxiii) Garbage system of refuse disposal; (xxxiv) home safety; (xxxv) road safety; (xxxvi) cremation; (xxxvii) garden cities.

This book is much more than a survey of progress in Public Health in Britain during the last few years. Rather it may be described as an outline of the best elements of current practice of the Health Departments of the major local authorities. It is, however, no formal exposition of administrative methods, for scientific progress towards prevention of disease is always related to the practice described.

Dr. Burn is an outstanding member of the younger school of medical officers of health who have long developed their interest in social affairs and have refused to be diverted by onerous administrative duties. It is amply clear from this book that the forebodings of so many health officers at losing their hospital work and many of the personal health services, under the National Health Service Act, are not fully justified. The vast majority of the subjects dealt with in this book are still in the particular, if not exclusive, province of the medical officers of health.

Over half the book is devoted to the health of children and their mothers—a proper proportion for any exposition of preventive medicine. For the rest, there are chapters on rural epidemiology, tuberculosis, prevention of infectious disease, and other subjects concerning which public health authorities are taking action for the benefit of the community. The chapters on the physical environment as influencing the health of the people are relatively short, a welcome realization of the extent to which the balance of public-health activity has swung away from sanitation. Nevertheless, it is strange in a book on public health not to find a chapter on housing. Perhaps because of the virtual

cessation of slum clearance due to the war, this subject of housing has passed into the background of the health officers' work. There is, of course, incidental reference to housing in many parts of the book and in a study confined to "recent advances" the author cannot cover every subject.

There is no other book which deals with these subjects from the point of view of a medical officer of health, so that reference will repeatedly be made to it by postgraduate students and practising health officers. It is therefore disappointing to find such an inadequate index. It is understood that the original index was much more comprehensive but that paper shortage finally determined a drastic reduction. This defect will no doubt be remedied in future editions.

Alan Carruth Stevenson

## 1268 Report of the County Medical Officer of Health and School Medical Officer for the Year 1946

London County Council. London, London County Council, 1947. 86 pages. 25 x 17 cm. 2s. [£0.1]

Annual reports of medical officers of health in this country are not on the whole very imaginative, nor are they light reading. Indeed, considering the care devoted to their preparation, and the masses of information, so significant to an understanding of social affairs which they contain, it is a great pity that the presentation is such as to deter the prospective reader. It must be said that this report of the County Medical Officer of Health of London is a good example of this tendency—packed with thought-provoking information but difficult, oh so difficult to read from cover to cover.

1946 was a very difficult year: a year of shortages of staff, particularly of nurses and hospital domestic workers; of work under difficult conditions in emergency or partly damaged buildings; and of housing shortages. During the year the population of the area of London County Council (L.C.C.) rose by 500,000 to 3,000,000, 75 % of the pre-war population, and this did not decrease problems of accommodation in houses, schools or hospitals.

In spite of all this, the work of the health department was further developed and new enterprises were launched in several directions. The County home-midwifery service was greatly extended and gas/air anaesthesia introduced in domiciliary midwifery practice. Even in the understaffed hospitals, the number of confinements increased above the pre-war figures. When so high a proportion of all confinements (probably about 50 %) are conducted by one or other council service, the health department is entitled to credit for their share in the low maternal mortality of 1.26 per 1000 live births. Only 0.33 per 1000 of the total is accounted to puerperal sepsis. These are the lowest figures ever recorded and compare favourably with those for the rest of England and Wales.

Infant mortality also fell to a new low level of 38 per 1000 live births, and child mortalities at all higher ages were also lower, mainly due to decrease in incidence and case mortality of whooping cough, measles and diphtheria.

This tale of reduction of mortalities in different groups and from specific causes could be continued indefinitely; certainly as far as statistical indices are considered the health of all London continued to improve.

One of the interesting developments of hospital work in London during the war was the much closer co-operation of the voluntary and the "L.C.C." hospitals. This showed itself not only in grouping of specialist facilities in units staffed jointly but in mutually advantageous arrangements for the teaching of nurses and medical students. The war-time association of teaching hospitals and council hospitals has been so advantageous as to be continued since the war and it is now to be perpetuated by an arrangement under the National Health Service. By this the special privileges accorded to the governing bodies of teaching hospitals is to be extended to include associated hospitals. This excellent arrangement will allow the London teaching hospitals to have properly balanced teaching material for the medical students and for the better all-round experience of nurses.

The School Medical Service of the London County Council is an enormous undertaking also controlled by the County Medical Officer and directed by a Principal Medical Officer. London is by far the largest unit of School Medical Service in the world (334,784 pupils in 1946), and that service is severely handicapped by the

dreadful old school buildings and medical inspection rooms which are still all too common. By delegation of authority to five divisional medical officers some of the disadvantages of unwieldy size are avoided. In two ways the London school medical work is unique: a high proportion of medical inspection and treatment is carried out by part-time practitioners, and most of the follow-up work (done by school nurses elsewhere) is the responsibility of voluntary care committees. These two differences can hardly fail to mitigate the "official" atmosphere inevitable to such a large undertaking. Perhaps the best vindication of the service lies not in the many tables showing reductions of incidence of this disease or that, but in the figure of 72.9% which is the proportion of routine inspections at which the child's parent was present in response to invitation.

Nearly half of all children have their midday meal in school and 93.14% of children in primary schools have one-third of a pint of milk free each day.

It is quite impossible to abstract further these eighty-three pages of closely packed information or even to mention the many activities of the London County Council special clinics, hospitals and schools. Perhaps enough has been said to convince a doctor interested in social medicine who is visiting London that he should try to see personally some of the activities of its Health Department.

A. C. Stevenson

## RADIOLOGY

### 1269 Certain Aspects of the Action of Radiation on Living Cells

*British Journal of Radiology*. London, British Institute of Radiology, 1947. (Supplement No. 1. Report of London Conference held May 13-14, 1946.) 146 pages; illustrations. 25 x 18 cm. 15s. 6d. [£0.775]

First Session: A. A brief survey of the physical processes involved in the absorption of radiation by living cells. B. The action of radiation on viruses. Second Session: The action of radiation on dilute aqueous solutions. Third Session: The action of radiation on chromosomes. Fourth Session: The effects of radiation on germ cells with special reference to man. Index.

The Editorial Board of the *British Journal of Radiology* is to be congratulated on its new departure—styled "Supplement No. 1"—which, in every way, adheres to the high standards of its parent journal. As its rather unwieldy title implies, the *Supplement* reports the proceedings of a two-day Conference held in May 1946, under the auspices of the British Institute of Radiology in London.

The mode of action of ionizing radiations was discussed by some 18 speakers, all men of eminence in their own spheres, who presented original papers on highly specialized subjects, covering the scientific hinterland of medicine. For this reason, the general medical reader may find the genetics and radiochemistry in this volume rather heavy going. However, there are at least two articles (on Viruses, by Dr. Roy Markham; and The Effect of Radiation on the Normal and Malignant Cell in Man, by Dr. P. C. Koller), which are of great general interest. The rest of the subjects are extremely important to radiologists, and especially to radiotherapists; and, of course, to those studying these special subjects, which I propose to review seriatim.

The Conference divided itself into five main headings. First, a comprehensive survey of the physics of radiation absorption: this is very well done and constitutes a summation of the advances of knowledge in this subject. After this, follow papers on the action of radiation in four special cases: Viruses; Dilute Aqueous Solutions; Chromosomes; and, finally, Germ Cells, with Special Reference to Man.

The section on viruses is of obvious importance in view of the role of viruses in the causation of tumours. It is interesting to note how we have advanced since the days when bacteriophages were the subject of controversy, and their discoverers subject to ridicule. Since that time, phages have been photographed with the electron microscope, and some have been shown to have a shape similar to a tadpole. Their discovery was made in England and France independently by Twort and d'Herelle. In the symposium under discussion are two papers by French workers on research done during the occupation of France. It was

gratifying to find good general agreement on parallel work conducted independently in the two countries.

The section on Dilute Aqueous Solutions has important bearings for the radiotherapist, since every malignant cell is approximately 90% water; and advances in this subject throw much light on the indirect effects of radiotherapy. This is particularly true of the effects on enzyme solutions, and one feels that a little more emphasis might have been placed on Mitchell's work on the conversion of ribose into desoxyribose nucleic acid.

The third section is mainly concerned with chromosome breakage and interchange, and is of a very high standard indeed; to the radiotherapist, Dr. Koller's paper will have an especial appeal.

The final section, on The Effects of Radiation on Germ Cells, includes a discussion on the occupational hazards of radiology, with particular regard to the fertility of workers in this field. Laboratory work is mainly carried out on the smaller mammals and on various insects (*Drosophila*, *Habrobracon*, and the like), and conclusions drawn from these creatures are not necessarily valid for the larger mammalia. Fortunately, the rather alarming conjectures of the geneticists concerning sub-fertility have not, as yet, been borne out in the human race. We are reassured to read in the discussion which followed this section, that in rabbits (the largest mammals represented in the experimental animals) several normal generations have been bred from spermatozoa irradiated with 50 r to 100 r.

However, there remains a wide field of research in this direction, and a comprehensive survey of the size and number of congenital abnormalities, occurring in families of x-ray workers of all classes, would seem to be desirable: this is too large a subject to be dealt with in this review, as are most of the important questions raised in these papers.

The whole Supplement deserves the highest praise, both in format and content. It is a really important work—the best thing of its kind yet published. Every radiotherapist should buy, beg, borrow or steal this book, which fills an important gap in the literature of this difficult subject.

It is to be hoped that further Supplements will follow, and that they will be bound in the stiffer cover that they deserve. My own copy is already becoming well dog-eared from constant use.

Ronald Hadden

### 1270 Radium Dosage. The Manchester System

Edited by W. J. Meredith. Edinburgh, E. & S. Livingstone, Ltd., 1947. vii + 124 pages; 38 figures; 4 plates. 25 x 19 cm. 15s. [£0.75]

Part I. Clinical aspects. (i) General introduction; (ii) mould treatments; (iii) rules for line-source applicator treatments; (iv) rules for cylinder mould treatments; (v) interstitial treatments; (vi) dosage for cancer of cervix uteri. Part II. Physical aspects. (vii) The physical basis of the planar mould and line source systems; (viii) physical basis of the cylinder mould system; (ix) the radiation field of a continuous cylindrical applicator; (x) physical aspects of the interstitial treatments system; (xi) the calculation of dosage and an additional distribution rule for cylindrical "volume" implantations with radium; (xii) the use of radiographs for dosage control in interstitial gamma-ray therapy. References. Index. Appendix I, II.

The Radium Dosage system developed and used at the Christie Hospital and Holt Radium Institute, Manchester, has become firmly established and its wide use in this country provides forcible testimony of its value and reliability.

The present volume is really a collection of the various papers published from Manchester during the past thirteen years on the subject of radium dosage systems. An attempt has been made to link up the papers in such a way that a single dosage system has been elaborated to cover all three types of radium technique, i.e., mould, intracavitary, and interstitial. The book, like several of the original papers, is divided into two sections—Part I Clinical, and Part II Physical.

The first part is clearly and simply written and is devoid of formidable mathematical formulae. The well-known dosage tables and distribution rules are given for each technique described and a series of well-illustrated examples is furnished, based on the use of the National Radium Commission Standard types of radium container. The original dosage-graphs are in an appendix to the book and are given in the form of tables. Also included in the Appendix are useful tables concerning radon, areas and circumferences of circles and volumes of cylinders.

Part II of the book, on physical aspects, will appeal chiefly to physicists or radiotherapists fortunate enough to possess the requisite knowledge of mathematics.

The compilation of the book was a very bappy thought, as it makes available in compact form information which is of fundamental importance both to radiotherapists and others concerned with or in any way interested in radium therapy.

M. Lederman

## RHEUMATISM

### 1271 Rheumatism and Soft Tissue Injuries

James Cyriax. London, Hamish Hamilton Medical Books, 1947. 410 pages; 101 figures; 107 plates. 24 x 16 cm. £2 2s. [£2.1]

(i) Traumatic and rheumatic inflammation; (ii) referred pain; (iii) neuritis and perineuritis; (iv) the diagnosis of soft-tissue lesions; (v) the head, neck and scapular area; (vi) the shoulder region; (vii) the elbow, wrist and hand; (viii) thorax and abdominal wall; (ix) the alimentary tract; (x) diagnosis in backache; (xi) the treatment of backache; (xii) the sacro-iliac joint; (xiii) pain in the buttock and thigh; (xiv) the lumbar nerve-roots; (xv) the knee; (xvi) the leg, ankle and foot; (xvii) treatment by movement (1); (xviii) treatment by movement (2); (xix) anaesthesia and analgesia; (xx) functional pain; (xxi) the problem of rheumatism and non-specific arthritis; (xxii) doctor and physio-therapist. References. Index.

This book contains the author's views on soft tissue injuries and rheumatism. In spite of its name comparatively little consideration is devoted to the latter subject. Some of the views expressed are somewhat unorthodox and the pathological conceptions will be generally considered over-simple.

The technique of massage which is particularly associated with the author's name is well described, and the greater part of the book consists in an account of its application to the various parts of the body, which are classified topographically.

There are many good illustrations and the volume is beautifully produced. It is likely to be of more interest perhaps to specialist physicians and physiotherapists than to the rank and file, but it provides food for thought for all.

W. S. C. Copeman

## STERILITY

### 1272 Diagnosis in Sterility. The Proceedings of a Conference sponsored by the National Committee on Maternal Health, New York City

Edited by Earl T. Engle. Oxford, Blackwell Scientific Publications Ltd., 1947. xi + 237 pages; 43 illustrations. 23 x 15 cm. £1 5s. [£1.25]

(i) The semen specimen. Laboratory examination; (ii) clinical interpretation of the semen analysis; (iii) the testicular biopsy. A five-year survey; (iv) the role of the accessory glands in fertility; (v) chronic hemospermia. Origin of the bleeding and treatment with estrogen; (vi) diagnosing the endometrial biopsy; (vii) interpretation of the basal body temperature curves; (viii) interpretation of post-coital examinations of cervical mucus; (ix) history taking for the infertile couple; (x) an interpretation and evaluation of tubal patency tests; (xi) reflections on a working hypothesis concerning a mechanism of sterility; (xii) so-called "pelvic congestion" in relation to sterility; (xiii) summary of the conference.

The Proceedings of the Conference on problems of human fertility held under the auspices of the National Committee on Maternal Health, in January 1945, are presented in this volume.

Five papers on the male factors—the semen specimen (J. MacLeod), its clinical interpretation (F. A. Simmons), testicular biopsy (C. W. Charny), the role of the accessory glands in fertility (C. Huggins), and chronic haemospermia (D. F. McDonald)—were read and discussed. The seven papers on the female aspect were: endometrial biopsy and its diagnosis (A. T. Hertig), basal body temperature curves (P. Tomkins), the post-coital test (W. W. Williams), history taking for the subfertile couple (W. H. Cary), tubal patency tests (N. F. Miller), a working hypothesis of the mechanism of sterility (A. T. Kenyon) and "pelvic congestion" in relation to sterility (H. C. Taylor). Finally, one of the leading authorities on the subject—Dr. John Rock—gave a clear and succinct summary of the Conference. Three of the points from the various papers that he stressed were: the diagnosis of necrospermia is not usually a very important one,

the need for a larger series of examinations of actively-procreating men in order to crystallize the various reference points for the consideration of semen, and the need for tactful handling of the husbands as there is so little to be done about very defective males.

On the female side, Dr. Rock said he was far from being impressed by the various treatments suggested to produce ovulation among the 3 to 5 per cent. of women who come to sterility clinics and are found to be anovulatory. Of mittelschmerz, it was still uncertain whether it came during the enlargement of the follicle when the cortex is being stretched, or when the cortex breaks, or with the impact of bleeding on the peritoneum. Of certain of his own cases he says: "I have come to the point of offering exploratory operation to any couple whose mating has been infertile for five years, and in whom there is no demonstrable cause for sterility. I will try a few endocrines here and there for two to three months, while they are making up their minds, but I think there is a great field for careful surgery in these cases."

The above papers, each followed by free and thorough discussions, go to comprise this volume of the Proceedings, which covers the various aspects of the subfertility problem.

Since this meeting there have been two more recent conferences under the aegis of the American Society for the Study of Sterility in June 1947, and February 1948. At the former, research on bialuronidase, an enzyme of the mammalian testes and sperm, came prominently into the limelight. The Proceedings of the latter meeting have not yet been published, so that the degree of progress made since the 1945 Proceedings under review is difficult to assess, though there are many gaps in our present knowledge and much scope for research.

Cedric Lane Roberts

## SURGERY

### 1273 Surface and Radiological Anatomy for Students and General Practitioners

A. B. Appleton, W. J. Hamilton & Ivan C. C. Tchaperoff. Second Edition rewritten by A. B. Appleton, W. J. Hamilton & G. Simon. Cambridge, W. Heffer & Sons Limited, 1946. viii + 332 pages; 390 figures. 25 x 19 cm. £1 11s. 6d. [£1.575]

I. General Anatomy and Methods. II. The Upper Limb: (i) Shoulder and arm; (ii) elbow, forearm and hand; (iii) vessels and nerves. III. The Chest and Back: (iv) Thoracic wall; (v) thoracic contents; (vi) physical examination of the thorax; (vii) great vessels; (viii) oesophagus. IV. Abdomen: (ix) Abdominal wall; (x) physical examination of the abdomen; (xi) abdominal contents; (xii) perineum; (xiii) deep blood-vessels of the abdomen. V. Head and Neck: (xiv) General features; (xv) the neck; (xvi) special organs and regions; (xvii) vessels and nerves; (xviii) the brain and its associated vessels; (xix) radiology. VI. The Vertebral Column. VII. The Lower Limb: (xx) Buttock and thigh; (xxi) region of the knee; (xxii) leg and foot; (xxiii) vessels and nerves. Appendices. Index.

The second edition of this book, written by three distinguished teachers from one scottish and two London medical schools, offers a new and inspiring approach to the study of anatomy. The radiological exposition of the skeleton and internal structures presents anatomy from a new and curiously realistic viewpoint. The projection on the surface of the deeper structures and their relation to the bony landmarks of the living body are of particular value in applied and clinical anatomy. The work should be no less valuable to the anatomist than to the radiologist and the clinician. The body is treated systematically, and its formal anatomy is presented in a novel, striking, and eminently truthful way. Many of the diagrams are highly original and strike home the anatomical points which they illustrate in so dramatic a fashion, that anatomical statements which have, from too frequent repetition in purely anatomical works, lost to the student their freshness, regain life and interest. This is really three-dimensional anatomy.

The book will also be valuable to the radiologist as well as to the clinician or to the students of anatomy, for by anatomical exposition the radiologist, too, is reminded constantly that his study is a three-dimensional one, and that anatomical substance underlies the shadows on his film.

Ian Aird

## 1274 Ambulatory Proctology

Alfred J. Cantor. London, Hamish Hamilton Medical Books, 1946. xv + 524 pages; 281 figures. 24 x 16 cm. £2 2s. [£2.1]

(i) Clinical anatomy; (ii) diagnosis; (iii) anaesthesia and analgesia; (iv) pre-operative and postoperative management; (v) pediatric proctology; (vi) pruritus ani; (vii) cryptitis and papillitis; (viii) anorectal fistula; (ix) perianal and perirectal abscesses and infections; (x) anal ulcer; (xi) hemorrhoids; (xii) prolapse and proctitis; (xiii) colitis; (xiv) diagnostic methods; (xv) enterocolitis and colitis; (xvi) bacillary dysentery; (xvii) tuberculous; (xviii) lymphogranuloma venereum; (xix) venereal diseases; (xx) intestinal parasites; (xxi) constipation; (xxii) melanosis coli; (xxiii) diverticulosis and diverticulitis; (xxiv) benign tumours; (xxv) multiple adenoma; (xxvi) malignant neoplasms; (xxvii) pilonidal dimple, sinus, cyst, and abscess; (xxviii) coccygodynia; (xxix) rectal stricture and anal stenosis; (xxx) anal incontinence; (xxxi) foreign bodies and rectal trauma; (xxxii) electrosurgical techniques. Index.

It is curiously antithetical that in the USA where specialization is narrowing perhaps more rapidly than elsewhere, a book should be produced which seems to make a specialty more accessible to the general physician. At first sight it would seem that it is a pity to distinguish arbitrarily those diseases in any field which require hospitalization from those which do not. The volume must perhaps be regarded rather as an argued plea for the more frequent treatment of rectal diseases in the consulting room. It is precisely in this particular that the book will meet with some criticism from British proctologists. There are no doubt advantages to be gained from the ambulatory post-operative treatment of certain rectal conditions, since the erect posture certainly allows for a free drainage, but in illustrating extensive and complicated procedures such as the treatment of deep pararectal abscesses in a book with this title, the author is perhaps inclined to treat rather lightly a most distressing and recurrent variety of ill-health, and one in which an inadequate operation is almost certain to fail in its purpose. Even the operation of haemorrhoidectomy is fully considered and three methods are described for use presumably in the ambulant patient.

The therapeutic measures described in the volume are, however, considered in such detail that it makes one wish that the author had not restricted himself to the ambulatory branch of his specialty. Diagnostic methods, too, are dealt with in the most satisfying fashion and, as a guide to rectal diagnosis and a manual of minor treatment, the volume is well worth its place in the practitioner's library.

Ian Aird

## 1275 British Surgical Practice. Volume 1

Under the general editorship of Ernest Rock Carling & J. Paterson Ross. London, Butterworth & Co., Ltd., 1947. xxxi + 536 pages; 228 illustrations; 2 plates. 25 x 17 cm. £3

(i) Abdominal emergencies; (ii) abdominal pain; (iii) abdominal wall; (iv) abortion; (v) abscess; (vi) achlorhydria and appetite; (vii) acidosis; (viii) actinomycosis; (ix) adhesions and cicatricial stenoses; (x) adhesions (pleural) in pulmonary tuberculosis; (xi) adiposity; (xii) adrenal glands; (xiii) after-care—introduction; (xiv) after-care—follow-up; (xv) after-care—methods and value of massage; (xvi) after-care—on return home; (xvii) after-care—post-operative; (xviii) after-care—remedial and occupational therapy and rehabilitation; (xix) air passages; (xx) allergy; (xxi) amoebiasis—amoebic infection of intestine (pathology); (xxii) amoebiasis—amoebic infection of intestine (surgery); (xxiii) amoebiasis—liver abscess and pathology of amoebiasis other than intestinal; (xxiv) amputations; (xxv) amyloid infiltration (amyloidosis); (xxvi) anaesthesia—general; (xxvii) anaesthesia—local infiltration; (xxviii) anaesthesia—regional; (xxix) angina pectoris; (xxx) angina pectoris (management); (xxxi) anxiety states; (xxxii) appendix—tumours of; (xxxiii) arteries; (xxxiv) artificial pneumothorax; (xli) artificial pneumothorax; (xlii) aseptis and asepsis; (xliii) autonomic nervous system—introduction; (xliv) autonomic nervous system—anatomy; (xlv) autonomic nervous system—arteries. Index to Volume 1.

This work, which was begun during the difficult days of the war, has been awaited with eagerness and, if we are to judge by this first volume, will now be welcomed by many open bookcases. It is a first-rate presentation of modern British surgical practice. The names of the editors-in-chief are sufficient guarantee that the material is all up-to-date, accurate and well arranged, and a perusal of any or all of the articles confirms this view.

The arrangement of the articles is alphabetical and this volume deals only with the letter A, but in it are included many important and valuable contributions. The two sections dealing with the surgery of the arteries (by Learmonth & Telford), that on arthritis (by Norman Capener), and on appendicitis (by Nuttall) are outstanding contributions. Excellent too are the articles

on anaesthetics, on amputations and on aftercare. The last-mentioned subject is dealt with from every aspect by a group of experts. There is a short 6-page section by Dr. Lindsey Batten entitled "On return home" which particularly appealed to the reviewer as showing such sanity and common-sense as is too often absent in the rush of surgical work. We would recommend every young (and also older) surgeon to read and re-read this short section, for it may do his patients good.

The illustrations are excellent and help the text considerably. Sufficient references are given to point the reader to more extensive accounts of the subject under review.

The editors-in-chief have taken a wide view of the subject and have called in several physicians to help their surgical colleagues.

The index is elaborate and, if anything, errs somewhat on the side of profuseness, but that is in the right direction. However, we think a certain amount of valuable space is wasted in several instances by the long initial list of headings at the beginning of each article. Readers of this volume will have their appetites whetted for the future instalments of this comprehensive and valuable work.

V. Z. C.

## 1276 A Synopsis of Orthopaedic Surgery

A. David Le Vay. London, H. K. Lewis & Co. Ltd., 1947. vii + 242 pages; 55 illustrations. 23 x 16 cm. 15s. [£0.75]

(i) Systemic skeletal diseases; disorders of osteogenesis; (ii) systemic skeletal diseases; disorders of adult bone; (iii) local diseases of bone; (iv) local diseases of bone; (v) affections of joints; (vi) affections of joints; (vii) affections of joints; (viii) affections of joints; (ix) hip and disorders. Index.

Synopses in general have a limited appeal. There are many students who find difficulty in assimilating such a mass of concentrated facts. A synopsis of orthopaedic surgery, moreover, if wrongly directed and used is a potentially dangerous form of teaching; for in this specialty, perhaps more than in any other branch of surgery, a knowledge of the facts forms only a part of the necessary equipment. The development of a sound and balanced judgement in the choice of treatment and a knowledge of the imperative necessity for detailed supervision of after-treatment are of supreme importance. To accumulate a mass of facts from a synopsis while neglecting the development of such a balanced judgement, often leads to the knowledge being misapplied.

Mr. Le Vay is clearly well aware of these difficulties. In his preface he warns the reader that in assimilating the facts presented he must not lose sight of the necessity for considering each patient as an individual problem, to be individually assessed from every aspect, before deciding on a plan of treatment. His book is addressed only to the more senior undergraduate, and to the postgraduate student reading for the higher examinations. This is wisely so, for to read it with advantage the student must have already attained a reasonable standard of orthopaedic knowledge and should have had some experience in the orthopaedic wards and the out-patient department.

To those who fall into this category the book will undoubtedly prove of very great value. For its size it is remarkably complete, and right up to date. This is particularly noticeable in those sections dealing with some of the more difficult orthopaedic problems, closely studied and now properly understood only in comparatively recent times. Such conditions as sciatica and low back pain, costo-clavicular compression, prolapsed cervical disc, and peripheral nerve injuries have been dealt with in a well-balanced, logical manner. The conclusions and recommendations are generally in accord with the most enlightened modern opinion. Indeed, there is very little in the subject-matter which calls for criticism.

In discussing the treatment of congenital talipes equinovarus in infants perhaps more mention might have been made of the use of plaster of Paris as a method of maintaining the over-corrected position. There are many surgeons who cannot accept the dogmatic assertion that wasting of the calf muscles results only from immobilization by plaster of Paris. Again, in the discussion on severed flexor tendons within the digital sheath, more stress might have been laid on the desirability of avoiding suture of the tendon within the length of the fibrous sheath, and of using a long graft in order to place the suture-lines at the proximal and distal extremities of the sheath.

Illustrations have been avoided except where considered essential for clarity. Those included are in the form of simple line-drawings and are adequate for their purpose. That depicting the vertebral displacement in spondylolisthesis is misleading, for the fifth lumbar body is shown displaced forwards in relation to the fourth lumbar body as well as to the sacrum.

Except for the irritating frequency with which sentences are begun with a conjunction, and for an unwarranted looseness of terminology, such as the use of the word tubercle for tuberculosis, the style is easy to read; particularly so for a synopsis.

The author is to be congratulated on having produced a comprehensive and balanced summary of a relatively-new and constantly-advancing speciality in such a small compass.

H. Osmond-Clarke

## 1277 The Appendix

R. J. McNeill Love. London, H. K. Lewis & Co. Ltd., 1947. 186 pages; 54 illustrations. 19 x 12 cm. 12s. 6d. [£0.625]

(i) Historical; (ii) anatomy; (iii) aetiology; (iv) diagnosis; (v) differential diagnosis; (vi) treatment of the appendix mass, and general peritonitis; (vii) appendicectomy; (viii) post-operative complications; (ix) appendicostomy; (x) chronic appendicitis; (xi) less common diseases of the appendix; (xii) obstetrical and gynaecological considerations. Index.

Nearly every year sees some new book on the appendix published, and this is quite as it should be, for appendicitis accounts for more acute abdominal emergencies than all other causes put together, and advances in treatment are constantly being made.

This little book by a well-known surgical author is well produced and nicely written, and in a brief compass of twelve short chapters gives the essential facts as to the clinical symptoms, diagnosis and treatment of the various disorders of the vermiform appendix. We can recommend it as a sound presentation of present-day views, with that slight emphasis on the so-called "delayed" operative treatment which is perhaps needed as an antidote to the "immediate operation in every case" attitude.

We have little to criticize, but in two points we are not in complete agreement with the author. We have found that the triangle of hyperaesthesia in acute appendicitis is not like that in fig. 12 but has a horizontal upper limit at the level of the umbilicus; sometimes when the appendix has perforated the hyperaesthesia does not extend up so far. The second point is concerning the treatment of actinomycosis in the appendix region. The author states that "massive doses of penicillin are worthy of trial". We should go further than this and say that large doses of penicillin should be continued without intermission for several weeks at least. If this be done the actinomycotic mass will very likely gradually disappear completely. In any case there ought never be the need to perform any excision or short-circuit.

The author rightly points out that pseudo-myxoma of the peritoneum may be caused by a persisting perforation of the appendix; the reviewer vividly remembers a case in which a male patient presented himself with a large mass filling the pelvis and causing a supra-pubic tumour which simulated a distended bladder. This proved to be a large pseudo-myxomatous mass which had its origin in a chronic perforation of the vermiform appendix.

We should like to see a reference to Willard Parker in the first (historical) chapter, and we were sorry to see Ochsner's name spelt wrongly in six places.

The reader of this book will learn a few facts of general information, e.g. how the north american Indian wakes up a sleeping person, and why unmarried women sometimes ask to have their appendix removed.

V. Zachary Cope

## 1278 Chronic Structural Low Backache due to Low-back Structural Derangement

R. A. Roberts. London, H. K. Lewis & Co. Ltd., 1947. v + 105 pages; 46 plates. 25 x 19 cm. £2 5s. [£2.25]

(i) Defective ossification of the Pars Interarticularis; (ii) group A: cases of "spondylolisthesis"; (iii) group B: cases of "spondylolysis"; (iv) group C: cases of "unilateral spondylolysis"; (v) group D: cases with upper lumbar defects; (vi) group E: cases with radiological evidence of defects of ossification in the articular processes; (vii) group F: cases with various radiological changes; (viii) group G: cases with no definitely recognisable radiological changes; (ix) the significance of defects of ossification in the neural arch; (x) the significance of

the histories of chronic backaches; (xi) the significance of oedema in overstrained soft tissues; (xii) neuro-vascular and "visceral" symptoms; (xiii) low-back structural derangement; (xiv) treatment from the structural aspect; (xv) the medical profession and the chronic backache. Index.

Chronic structural low backache is, in this book, attributed mainly to abnormalities of the "pars interarticularis"—conditions known as spondylolysis and spondylolisthesis. It is suggested that these abnormalities are much more frequent than is generally appreciated. Many figures are quoted to support this view. Another reason given for failure to recognize these structural derangements is that frequently they are visible *only* in x-ray plates taken obliquely. An interesting contention is that these defects are not due to failure of fusion but to "deossification" as a result of chronic strain. The symptoms are attributed to the chronic strain, of which the structural derangement is a manifestation. Considerable importance is attached to oedema as a cause of localized pain in the back and also of root pain. Relief following saline injections—said by some to invite a psychological rather than a physical explanation of the pain—is due to dilution of oedema, aiding its more rapid absorption.

There is nothing strikingly new in this book—except perhaps some points regarding the cause and significance of the laminar defects. The author quotes other writers who have emphasized the frequency of these defects and also that oblique views are necessary to see them. To say the book contains nothing new is, in a way, a form of praise, as a better interpretation of much that is already known is urgently needed.

There are 137 figures, all x-ray plates, showing various abnormalities of the pars interarticularis; many of these are traced for ease of interpretation.

The last chapter—comprising one fifth of the text—is a general attack on the attitude of the profession to sufferers from backache, and a particular attack on psychiatrists for convincing ignorant "orthopaedists" and others to swell the ranks of those suffering from so-called psychosomatic disorders. This is excellent, the best part of the book and probably what justified its production. There are no half tones in this chapter. The medical officer (or specialist) painstaking enough to record physical signs and make a diagnosis of one of the many causes of backache, including those mentioned by the author, does not exist. All neuropsychiatrists are psychiatrists only and have heard of "anxiety state", but do not believe in physical signs in the diagnosis of disc lesions.

The book is interesting and stimulating. If it succeeds in making the profession as a whole more patient and interested in the considerable proportion of the population that suffers from backache it will serve a useful purpose.

J. C. Scott

## TOXICOLOGY

### 1279 Poisons, their Isolation and Identification

Frank Bamford. Second Edition, revised by C. P. Stewart. London, J. & A. Churchill Ltd., 1947. viii + 304 pages; 23 illustrations. 22 x 14 cm. £1 1s. [£1.05]

(i) Introduction: organization and equipment; (ii) classification of poisons; (iii) volatile poisons; (iv) volatile poisons (*continued*); (v) common metallic poisons; (vi) other metals; (vii) corrosive acids and alkalis; (viii) non-volatile organic poisons (alkaloids); (ix) non-basic organic poisons; (x) the isolation of non-volatile organic poisons; (xi) a systematic scheme for the identification of alkaloids; (xii) systematic testing for non-basic poisons; (xiii) miscellaneous poisons; (xiv) drugs of addiction. Index.

Soon after its publication in 1940, the first edition of this book had established itself as a reliable and most useful guide to the isolation and identification of poisons encountered in toxicological practice. The demands of chemists and clinical pathologists working in this field are exacting, methods must be described explicitly and must, above all, be of proven reliability. Bamford designed the volume as a practical handbook in which each test and procedure had been personally used in the examination of viscera for poisons and its ready acceptance as the standard british manual on the subject has indeed justified the high aims of the author.

In the second edition, under review, Dr. Stewart has faithfully preserved the book's outstanding characteristic. The text is little altered, the number of pages being indeed reduced by 40, but this is achieved by an addition of 5 more lines per page and the

exclusion of a separate author index. The short section on gaseous poisons is new and useful additional matter is noted under the quantitative determination of hydrocyanic acid, general procedures in toxicological analysis and under arsenic. A figure demonstrating the use of the Hartridge reversion spectroscope replaces that of the Duboscq colorimeter in the former edition. These are all improvements but, in the opinion of the reviewer, the value of the book has been enormously enhanced in this second edition by the judicious use of italics and sub-headings in bold type which facilitate quick reference and improve the general readability of the text. There is also evidence of careful trimming of several paragraphs with elimination of irrelevant matter, and the reviewer is glad to notice that the error in the chemical equation on p. 88 of the old edition has been perceived and corrected (p. 80).

Useful tabular rearrangement has been made of the barbiturates, and the section on the cardiac glycosides has been revised. The inclusion of notes on the preparation of reagents for alkaloid tests removes what was a blemish in the original work.

Altogether Dr. Stewart and the publishers are to be congratulated upon the high standard they have achieved and the book can be confidently recommended as essential on the shelves of any laboratory engaged in toxicological work.

C. Rimington

## TOXICITY OF METABOLITES

### 1280 Detoxication Mechanisms. The Metabolism of Drugs and Allied Organic Compounds

R. Tecwyn Williams. London, Chapman & Hall Ltd., 1947. viii + 288 pages. 22 x 14 cm. £1 5s. [£1.25]

(i) Introductory and historical; (ii) the metabolism of some aliphatic compounds and cyclohexane derivatives; (iii) the metabolism of aromatic hydrocarbons; (iv) the metabolism of halogenated aromatic hydrocarbons; (v) the metabolism of phenols; (vi) the metabolism of aromatic alcohols, ethers, aldehydes, ketones and amides; (vii) the metabolism of aromatic acids; (viii) the metabolism of organic cyanides; (ix) the metabolism of the aromatic nitro, amino and azo compounds; (x) the metabolism of sulphones, sulphonic acids and sulphonamides; (xi) the metabolism of terpenes and camphors; (xii) the metabolism of heterocyclic compounds; (xiii) the metabolism of organic compounds of arsenic; (xiv) theoretical considerations and conclusions. Bibliography. General Index.

It is unfortunate that, by the use of the title *Detoxication mechanisms*, Dr. Williams has given new life to a misnomer which showed some sign of dying a natural death. The sub-title of this book, "the metabolism of drugs and allied organic compounds", is at once a more satisfying terminology and a more true expression of the field covered by the author.

The aim of the author has been to summarize the literature over the whole field of drug metabolism for a period of just over one hundred years. The inevitable result is that the book, at times assumes the character of a catalogue, albeit a most useful catalogue. Perhaps Dr. Williams might have held more readily the attention of the general biochemical reader as opposed to the specialist in his own field if he had brought his last chapter, Theoretical Considerations and Conclusions, to the beginning of his book and had then attempted to relate the detailed findings on individual compounds to his theoretical background. There is no doubt that he is right in rejecting both the chemical defence hypothesis and the surface tension hypothesis as a working basis for further progress, but there is too little indication, in the main body of the book, that the general metabolic pattern of the animal body is the governing factor controlling the fate of all metabolites, either natural or foreign. Surprisingly little information is given about kidney function and, on the whole, one is left with the impression that the animal has been regarded by many workers as an interesting toy capable of chopping complex molecules into curious shapes. Such comment is not so much a reflection on this book as upon the existence of an artificial barrier between intermediary metabolism and drug metabolism which was erected over a period of years by the concept of specialized detoxication mechanisms. Dr. Williams might have done more to destroy this barrier.

These are the criticisms of a general reader who found several chapters of this small book of 250 pages rather heavy reading; they do not detract from the value of the book as a source of information which, within the limits set by the author, is concise, clear and reasonably complete. The book has brought together much scattered information and will be useful to the teacher or to the research student entering the field; it will also

save much searching of the literature by those workers who, without a detailed knowledge, suddenly find themselves faced with a problem in drug metabolism.

The book is provided with a general author index and a complete subject index which should make it a convenient source of reference. There are a few obvious printing errors and occasional formulae are badly printed or lack their full quota of bonds but on the whole the print is clear. It is unfortunate that the publishers should find it necessary to charge 25 shillings for a book of this size.

T. S. Work

## TUBERCULOSIS

### 1281 Dust and its Effects on the Respiratory System

George H. Gill. London, H. K. Lewis & Co. Ltd., 1947. viii + 50 pages; 17 illustrations. 22 x 14 cm. 5s. [£0.25]

With such a vast amount of published work on this subject, much of it indeterminate or equivocal, confronting the author, it must have been extremely difficult for him to choose what to include or what to omit. Mr. Gill has come down on one or other side of the fence on some debatable points, but that could hardly have been avoided in a condensed work of this nature.

The terms "Pneumokoniosis" and "Silicosis" are always a pitfall: pneumokoniosis embraces all forms of dust disease in the lungs and at whatever stage of the disease, silicosis is a subdivision applied to the disease resulting from exposure to silica dust. "Pneumokoniosis of coal miners" is another subdivision applied to the disease resulting from exposure to coal dust in which it is assumed, however, that silica plays a part. Pneumokoniosis is not an early stage of silicosis.

Possibly emphysema could be better described as a condition in which the lungs, their elastic, contractile power having been destroyed, become over-distended with unused or useless air. Here one is confronted by the author's own problem of compressing information, however.

Mr. Gill's reference to the electron microscope is timely; possibly this instrument would clarify the present unsatisfactory assessment of dust hazard in coal mines.

Altogether the author is to be congratulated for encompassing in a short summary so much well-selected, concise and pertinent information. For those, lay or medical, interested in dust disease this is an excellent "Primer".

E. Aslett

### 1282 Tuberkulöse Reinfektion beim Rinde und ihr Einfluss auf die Resistenz

E. Gräub, W. Zschokke, E. Saxer & H. Vonarburg. Basel, S. Karger, 1947. 82 pages; illustrations. 24 x 17 cm. Sw. fr. 12

(i) Einleitung; (ii) erste Versuchsperiode: 1932-1941; (iii) zweite Versuchsperiode: 1942-1947; (iv) Anhang.

Five calves subcutaneously infected with a bovine strain of attenuated virulence remained up to 4½ years resistant to subcutaneous infection with virulent strains. After subcutaneous infection with the avirulent bovine bacillus, a typical primary complex developed in three out of the five animals. One of the others showed bacilli only at the site of infection or in the regional lymph gland respectively. After virulent reinfection, however, a primary complex was found in one instance, whereas avirulent reinfection yielded only incomplete primary lesions, bacilli being recovered either from the site of reinfection or from a regional lymph node. After avirulent reinfection, latent tubercle bacilli were found in a lymph gland up to 24 months; after avirulent primary infection, up to 36 months at the site of infection. Repeated reinfection with a bovine strain of attenuated virulence proved a means of maintaining resistance to natural infection with virulent bacilli for years; (for example, 4 cows kept under observation for 4½-7½ years remained free of infection, in spite of immediate contact with tuberculous cows for 17-36 months). A local arrest of virulent bacilli at the site of reinfection could be demonstrated. They did not even reach the corresponding lymph glands. Animals infected with living avirulent bacilli became, as a rule, allergic and, although showing temporary fluctuation in the response, reacted to tuberculin—

the intradermal test being superior to the subcutaneous (thermo-) and optharmo-reaction. The subcutaneous test remains negative after spontaneous infection with human, avian and saprophytic acid-fast bacilli. A positive subcutaneous tuberculin reaction indicates infection with the bovine type. The subcutaneous reaction also depends upon natural or acquired resistance. With increasing resistance acquired by avirulent infection, tuberculin hypersensitivity vanishes, but may temporarily re-appear on the development of new active foci subsequent to avirulent reinfection. With regard to tuberculosis of the udder and infection of the milk, of the five calves infected with attenuated bacilli and reinfected in adult age, none developed chronic tuberculosis of the udder, at least within 4½ years, nor caused reinfection during pregnancy or lactation by any permanent excretion of tubercle bacilli through the milk, results which favour the conclusion that in infected cowsheds bacilli find their way into the milk after its excretion (for example, from infected faeces, vaginal mucus or infected straw-bedding).

The authors attribute the efficiency of avirulent infection, in inducing resistance, not only to the properties of the strain used, but also to their own *special technique*, consisting of repeated reinfection in *different areas involving ever-new groups of lymph glands*. If reinfections are always made in the same area the lymph glands already damaged by the first infection and previous reinfections will be unable to display their full tissue function in building up resistance (whatever this function may be).

An appendix deals with the question of the influence of pregnancy on reinfection. Out of four animals infected and reinfected with the avirulent strain, two were protected against virulent reinfection. The susceptibility of the two remaining animals is attributed to permanent excretion (during 1½ years) of *Brucella abortus* (Bang) with the milk, which predisposed the udder to infection—an observation which confirms the view of Roux, who regards *Brucella* infection as a general predisposition to udder-tuberculosis.

Finally, some experiments in guinea-pigs are reported which are supposed to show that avirulent infection, which leaves permanent changes at the site of infection, is superior in conferring resistance to virulent reinfection to those yielding none or only fugitive changes (as for example, with killed tubercle bacilli, "Antiphymatol", Friedmann bacilli and B.C.G. In this the authors fail to see that much depends here on the mode and frequency of application of the killed or avirulent bacilli, factors which they themselves have shown to be operative in their own experiments with cows, reported above.

## Shorter Notices

### Ocular Vertical Deviations

J. Ringland Anderson. London, British Journal of Ophthalmology, Ltd., 1947. Monograph Supplement XII. 108 pages; 37 illustrations. 25 x 17 cm. 12s. 6d. [£0.625]

The author, ophthalmic surgeon to the Royal Albert Hospital, Melbourne, includes in this monograph "a partial survey of the literature and an analysis of a series of 402 patients with horizontal and vertical defects of the concomitant and paralytic types." He gives an account of the action of the main ocular muscles as an essential basis for diagnosis and stresses the need for attention to the co-ordinated movements of both eyes together in arriving at an accurate diagnosis. In making this diagnosis he considers the study of diplopia a most useful guide. He regards the frequency of the occurrence of anomalies of the vertically acting muscles as much underestimated and notes the frequency of finding disorder of the vertical muscles in cases of "so-called concomitant strabismus."

Dr. Anderson's criterion for operative treatment is the disability resulting from an ocular palsy rather than the paresis itself, and he advises careful consideration of the possibility of spontaneous recovery. Although he does not attempt to describe the technique of orthoptic training, he suggests that it has an important position in the treatment of the majority of ocular palsies. He also gives concise accounts of various diagnostic tests (including a simplified routine for those not equipped with a Hess or projection apparatus) and short discussions of operative procedures.

P. W.

### Recent Advances in Medicine: Clinical, Laboratory, Therapeutic

G. E. Beaumont & E. C. Dodds. Twelfth edition. London, J. & A. Churchill Ltd., 1947. xii + 422 pages; 42 illustrations. 21 x 14 cm. £1 1s. [£1.05]

In this 12th edition of the *dayen* of the famous series, the authors have once again justified the title.

The chapter on chemotherapy has been rewritten and a new section added on synthetic antimalarial drugs. A new chapter has been added on the antibiotic substances, discussed both from the clinical and laboratory aspects. The chapter on vitamins has been considerably altered; in particular the sections on the vitamin B complex and vitamin K have been rewritten, and notes have been included on biotin, folic acid and dicoumarol. New articles deal with thiouracil, primary atypical pneumonia, infective hepatitis, homologous serum jaundice, bone marrow transfusion, the use of thiocyanates in the treatment of high blood pressure and the treatment of malignant disease by synthetic oestrogens. Chapter XIV, Blood and Urine Analysis, has been revised to include the latest procedures.

Unfortunately, in order to preserve the size of the volume certain sections, such as those dealing with the kidneys and diphtheria, have had to be omitted. However, such pruning is inevitable in a book of this kind if it is to retain one of its most useful features, namely ease of handling.

G. J. H.

### A Handbook of Midwifery for Pupil-Midwives, Midwives, and Obstetric Dressers

Comyns Berkeley. Thirteenth edition. London, Cassell & Company Ltd., 1946. ix + 456 pages; 88 illustrations. 19 x 12 cm. 12s. 6d. [£0.625]

Since 1906, this book, a standard work of its class, has passed through thirteen editions and twelve reprintings. While the book caters for the needs of those preparing for the examinations of the Central Midwives Board (for example, the chapter on hormones is in the present edition transferred to an appendix, as a result of the C.M.B. notification to examiners that pupil midwives need not be examined in this subject), it fulfils a wider function than that of an examination text. Authoritative answers are given to a wide range of problems, but, at the same time, clear and concise reasons are given for the validity of the answers.

The sections on treatment of unavoidable haemorrhage and on blood transfusion have been rewritten and a brief note on the Rh factor has been added.

A clear and full index adds to the value of the book.

P. W.

### Lunacy and Mental Deficiency. The Thirty-third Annual Report of the Board of Control for the Year 1946. Part I.

Board of Control. London, His Majesty's Stationery Office, 1947. 40 pages. 24 x 15 cm. 9d. [£0.0375]

Because of the changes which will result from the operation of the National Health Service which came into force in July 1948, this report is the last to be presented to Parliament in this form. The Board's administrative functions have now been transferred to the Ministry of Health.

The number of persons under care in 1946 was 146,444 and there were 6,009 more admissions during the year than in 1945. There has been a steady rise for several years in the number of admissions. Voluntary admissions (18,059) compare with 9,651 in 1938, and follow the development in both doctor and layman of a much greater awareness of the importance of early treatment.

There is an aggregate overcrowding rate of 13.1%; 15,170 beds were not available (10,417 being still diverted to wartime services, 3,080 unoccupied owing to shortage of staff, and 1,673 awaiting restoration or re-equipment). One of the most serious shortages is that of female nurses, but a slight improvement is evident in some hospitals.

It is a matter for satisfaction that, in the treatment of mental disorders, some form of physical treatment is used in every mental hospital to supplement psychotherapy and other methods. With regard to prefrontal leucotomy, some time must elapse before opinion can crystallize as to the efficacy of this form of treatment, but there is reason to hope that this operation offers a probability of relief and the possibility of recovery.

Emphasis is laid on the importance of occupational treatment for chronic patients. The shortage of social workers trained to undertake work in mental health is acute and the report suggests the need for a special course for training social workers for mental-deficiency services.

(i) Of fevers; (ii) the countess's powder; (iii) the Jesuits' powder; (iv) philosophical interlude; (v) the wonderful secret of the Englishman; (vi) the fever bark tree; (vii) the Botanical Institute of the New Kingdom of Granada; (viii) the breaking of the spell; (ix) scientific interlude; (x) poor man's quinine; (xi) the betrayal; (xii) rich man's quinine; (xiii) Hercules, the hydra, and the birds; (xiv) Bataan and Corregidor; (xv) of fevers.

### [1232] The Medical Writings of Anonymus Londinensis

W. H. S. Jones. Cambridge, Cambridge University Press, 1947. viii + 168 pages. 22 x 14 cm. 12s. 6d. [£0.625]

(i) Anonymi Londinensis Iatrica; (ii) Excursus I. The nature of Greek thought. II. The nature of Greek medicine. Index of *Notabilia*.

a position as the standard English work on neurology. Owing to the fact that seven war-years have passed since the 2nd edition, much revision has been necessary. The lessons of war have been no less in the neurological field than in others. New light has been thrown upon the nature of peripheral-nerve injuries and has entailed the rewriting of the relevant section. A new chapter is devoted to the nutritional disorders of the nervous system, based upon the unfortunate cases found in prisoner-of-war camps. Herniated lumbar intervertebral disk now occupies most of the space formerly devoted to sciatic neuritis. New sections have been added on equine encephalitis, myelopathy, the nervous complications of epidemic hepatitis, spinal radiculitis, and platybasia. The section on the psychological aspects of neurology has been recast and now includes the status of psychogenic symptoms, psychotherapy and psychometric tests. Like its predecessors, this edition is well supplied with illustrations and references, and the whole production is well up to the standard expected from this publisher.

G. J. H.

### Ulcer of the Stomach, Duodenum and Jejunum

Ralph C. Brown. New York, Oxford University Press; London, Geoffrey Cumberlege, 1946. iv + 104 pages; illustrations. 24 x 16 cm. 12s. 6d. [£0.625]

This book, reprinted from the Oxford Loose-Leaf Medicine, with pages similarly numbered, is a general review, on the lines of a text-book, of ulcer of the stomach, duodenum and jejunum. Sections are devoted to etiology, pathogenesis, morbid anatomy, symptoms, diagnosis and treatment. Gastric and duodenal ulcer are not clearly separated and often are dealt with together as peptic ulcer. Otherwise the statements are in general accord with the views held at the present time. A few cases are quoted briefly from the author's personal experience, and there are a few brief references to research by others. No new ground is broken. The figures, with the exception of the frontispiece, are contour-drawings from radiographs and illustrate clearly the well-known features of peptic ulcer.

Henry Tidy

### Traumatología Ocular de Urgencia

José Casanovas. Barcelona, Ediciones BYP, 1947. (Colección Española de Monografías Médicas, Volume 67-68.) 147 pages; 20 illustrations. 20 x 14 cm.

Dr. Casanovas, who is a member of the Faculty of Medicine in Barcelona, has written this short book to help medical men who are not specialists in ophthalmology but who may be required to give emergency treatment for eye injuries. The author begins by describing methods and apparatus for the examination of the eyes and for the location of injuries and foreign bodies in the eyes. Further chapters describe various eye injuries and their treatment. This book also includes Vol. 67-68 of the *Colección española de monografías médicas*, containing two original papers and reprints of five articles originally published in other journals.

### Symptoms and Signs in Clinical Medicine: an Introduction to Medical Diagnosis

E. Noble Chamberlain. Fourth edition. Bristol, John Wright & Sons Ltd., 1947. vii + 463 pages; 346 figures. 23 x 15 cm. £1 10s. [£1.5]

We welcome the 4th edition of this book, which first appeared in 1936, and which is very widely used by medical students beginning their work in the

wards. Dr. Noble Chamberlain surveys a vast ground in this introduction to medical diagnosis. The main chapters of the book cover the clinical examination of the patient and the methods of taking a history and of eliciting physical signs, and briefly discuss the differential diagnosis of the abnormal signs. This part provides a clear account of the basic essentials of clinical medicine. The later chapters of the book, which deal with subsidiary methods of investigation, medical operations, radiology and clinical pathology, bear little relation to the title, are too condensed and lacking in detail for the enquiring student, and are more open to criticism. The directions for some of the operations, such as bronchography, while given in some detail, are in fact incomplete. Fig. 287, showing a black-coated doctor performing a lumbar puncture on a sitting patient, watched by an unmasked attendant, should surely be excluded from an introductory volume for the student; and lipiodol is now rarely, if ever, used intrathecally in the localization of spinal tumours.

It seems a pity that these chapters take up space which might profitably be filled by an expansion of the earlier part of the book. A fuller discussion of the causation of some of the physical signs would be of great value, and several sections require revision. A more complete account is needed of the eye signs in thyrotoxicosis, distinguishing clearly between exophthalmos and lid retraction; the section on the diagnosis of diseases of the liver is inadequate (and infective hepatitis is not mentioned as a cause of hepatic enlargement); and a coloured plate of the common skin rashes should surely appear in a volume devoted to physical signs. Since the introduction of chemotherapy, the student will rarely see a case of lobar pneumonia in which the "fever and constitutional signs continue . . . for a week, and the pyrexia then subsides by crisis", and he will find it difficult to appreciate how alkalosis, by causing relaxation of the hypertonic stomach wall, can lead to a correct adaptation between the stomach and its contents, with the relief of gastric pain.

It might, at first sight, appear invidious to criticize a work which, by its popularity, has proved that it fills a need, but the more widely used a textbook, the more important it is that it should be as free from fault as possible.

M. L. Rosenheim

### The Sanitary Inspector's Handbook: A Manual for Sanitary Inspectors and other Public Health Officers

Henry H. Clay. Sixth edition. London, H. K. Lewis & Co. Ltd., 1947. xxii + 545 pages; 99 illustrations. 22 x 14 cm. £1 2s. [£1.1]

The range of knowledge required by modern sanitary inspectors is very wide and this book provides an excellent guide to the many facets of their work. The great increase in legislation and regulations dealing with public health, as well as the advances in the technology of hygiene and sanitation that have taken place since the previous edition, has entailed a thorough revision and the addition of a considerable amount of new material. This book serves two valuable purposes: it is the essential textbook for the prospective sanitary inspector and an invaluable work of reference in public health departments. The illustrations, many of which have been redrawn in this edition, are models of clarity and should be of much use to the student.

G. J. H.

### A Way of Life for the Handicapped Child: a New Approach to Cerebral Palsy

Elsie Collis. London, Faber & Faber Ltd., 1947. 183 pages; illustrations. 21 x 14 cm. 10s. 6d. [£0.525]

The handicapped child of this book is the victim of cerebral palsy; the author studied under Dr. W. M. Phelps in the USA and is the pioneer in Great Britain of his approach in the treatment of such children. The London County Council gave her every facility to carry out the treatment in one of their children's hospitals and this book embodies the results of a personal study of individual children over a four-year period. The opening chapters deal with etiology, types, signs and symptoms of cerebral palsy and the psychology of the child so afflicted. It is assumed that treatment should consist in training a different part of the brain to take over the function of the damaged areas and subsequent chapters deal with the control of specific movement, e.g. strengthening the abdominal and respiratory muscles, proceeding to voluntary attempts at head raising, correct sitting and trunk movements, and occupational therapy in which the application of trained movements to specific skill is stressed. It includes the activities of the normal child, such as sand games, playing with blocks, buttoning and unbuttoning, etc. There are many illustrations of mechanical aids and supports, such as chairs, tables and sliding boards, made to the author's own designs, together with examination charts and descriptions of physical exercises, with their accompanying music, for routine work.

The book concludes with an excellent summary of this new approach, emphasizing that children with cerebral palsy are not necessarily mentally defective and that, while there is as yet no known cure for the condition, with patience and understanding on the part of the therapist they may be trained to become normal and happy members of the community.

D. F. A.

### Health the Unknown: the Story of the Peckham Experiment

John Comerford. London, Hamish Hamilton, 1947. 144 pages. 19 x 13 cm. 7s. 6d. [£0.375]

Mr. Comerford tells in his preface how he read *The Peckham experiment* by Pearce & Crocker and resolved to write a simplified and shortened version for the non-scientific reader; his success has been uneven. Here and there unexplained scientific terms appear, simple popular "journalistic" alternates with polysyllabic passages and there are a good many intrusions of pseudo-philosophy, but on the whole the idea and the spirit of the Peckham Pioneer Health Centre are well caught and vividly if impressionistically presented. The book bubbles with uncritical enthusiasm which will irritate the scientific reader but is likely to achieve the author's intention of arousing the interest of the ordinary man and leading him on to further study of the subject.

Too often the opinions of the staff of the Centre are quoted as if they were the dogmatic statements of accepted authorities and there are places in which Mr. Comerford implies that the Centre itself is a final solution to social problems rather than a laboratory in which they can be studied, a claim which the staff themselves are wisely reluctant to make. Again, the author's sadly imperfect knowledge of British public-health and social-service work betrays him into belittling its actual success and its potentialities. Read with caution the book has real value but, unfortunately, it is designed to appeal to the less cautious class of reader.

John D. Kershaw

### Man and Animals: What They Eat and Why (A Manual of Nutrition)

Ben Dawes. London, Longmans, Green & Co., 1947. vii + 100 pages. 19 x 13 cm. 7s. 6d. [£0.375]

This is not, as might be imagined from the title, a work of a popular nature; for the author, Reader in Zoology at King's College, London, presupposes in the lay reader, for whom it is intended, a knowledge of chemistry and physics in relation to biology. It is an amplified excerpt from a projected large general work on animal biology and deals with the fundamental chemical and physical relations between the living animal and the food it eats. The subject-matter is divided into three sections, on protoplasm, on the nature of food, and on the uses of food. The author would seem to be somewhat over-optimistic in thinking that lay readers will have the patience and intelligence to master the necessary use of scientific terms and in hoping that it will serve "to increase an instructed public interest in the problem of why we eat what we do." It should however prove of value to students of biology, zoology and biochemistry and to research workers in the field of animal nutrition.

G. J. H.

### A Textbook of Dietetics

L. S. P. Davidson & Ion A. Anderson. Second edition. London, Hamish Hamilton Medical Books, 1947. xix + 517 pages; illustrated. 22 x 14 cm. £1 1s. [£1.05]

This book is directed mainly to the student and to the general practitioner and deals with the subject under three main headings: the physiology of nutrition, diet in periods of physiological stress, and dietetic treatment in established disease. The war-years have seen great developments in each of these branches and the modification of the text to include them has involved a not inconsiderable increase in its length.

In the section on the physiology of nutrition, the chapters on proteins and vitamins have needed the most revision; the former now includes an account of protein hydrolysates and the latter a discussion of the use of folic acid in macrocytic anaemia. In the second section a new chapter has been added on the treatment of starvation, a subject that came into prominence with the liberation of prisoners from the concentration and prisoner-of-war camps. A useful new chapter is the one on special feeding methods, which are dealt with in some detail. The section on the treatment of established diseases has been brought up to date by new articles on the use of globin insulin, on the dietetic treatment of peptic ulcer and on other topics. The final section which deals with tables, recipes and diet sheets, has been completely redrafted in the light of the most recent authoritative official figures. It also includes a new chapter on methods of carrying out dietetic surveys.

G. J. H.

### Essentials for Final Examinations in Medicine

John de Swiet. Third edition. London J. & A. Churchill Ltd., 1947. vi + 178 pages 19 x 12 cm. 9s. [£0.45]

This book, as the author explains in the preface to the 1st edition, is intended to aid the student in his last revision for "finals", and not to replace the standard text-books of medicine. It can only summarize for him the knowledge he should already have gained from them. In this edition new material has been introduced on penicillin, pellagra and related disorders, osteo-arthritis, chronic subdural haematoma and primary atypical pneumonia. An index has been added.

H. C.

### Food Poisoning: its Nature, History and Causation. Measures for its Prevention and Control

Elliot B. Dewberry. Second edition. London, Leonard Hill Ltd., 1947. xii + 246 pages; 58 illustrations. 22 x 14 cm. 17s. 6d. [£0.875]

Although the author of this book claims no originality for it, the 1st edition filled a gap in medical literature by presenting in one volume the fundamental facts relative to many kinds of food poisoning. Previously, in order to acquire this information an extensive search of many different sources was necessary. For those wishing to read more widely on any topic an extensive bibliography is appended to each chapter. This edition has been brought up to date by the addition of new material, including a chapter on staphylococcus food-poisoning, a type of illness which has been much to the fore in recent years. Interest is added to the text by photographs of some of the early investigators in this field. It is a pity, however, that the modern practice of carrying the illustrations to the edge of the page has been adopted, as this inevitably leads to their suffering damage under the extensive use that a work of this type is likely to get.

G. J. H.

### Propedéutica de Patología Circulatoria en las Profesiones

Domingo de Durán Arrom. Madrid, Ediciones Morata, 1947. 171 pages; 28 illustrations. 25 x 18 cm. 40 ptas.

Dr. Durán Arrom has published many works on cardiological subjects, of which he has made a special study. He here describes disorders of the heart and circulation caused by trauma, occupational diseases, or infection. He discusses preventive measures and questions of diagnosis, treatment and medico-social care. The book is clearly and simply written and well illustrated, and contains useful author- and subject-indexes.

V. E. C. M.

### Vital Statistics and Public Health Work in the Tropics, Including Supplement on the Genealogy of Vital Statistics

P. Granville Edge. London, Baillière, Tindall & Cox, 1947. xii + 268 pages. 22 x 14 cm. 15s. [£0.75]

The 2nd edition of this work consists of a 2nd impression of the original edition, complete with index, and with about 80 additional pages entitled "The genealogy of vital statistics". To those who have not yet seen the 1st edition of 1944 the reprint will be of value. It is primarily addressed to those interested in British tropical territories, but will be helpful to all who have to deal with problems of vital statistics in the tropics.

The new historical section, with its separate index, breaks new ground. It is not confined to the tropics, and sketches the whole development of vital statistics from the Babylonian to the British Empire. The author certainly succeeds in his purpose of showing that this science is "the lineal descendant of a really ancient family", but he does not attempt to relate its history to the social and economic conditions that produced it. The study is of necessity only a summary, and will provide the medical historian with much interesting material and many references.

D. T. Richnell

### Child Health and Development by Various Authors

Edited by Richard W. B. Ellis. London, J. & A. Churchill Ltd., 1947. viii + 364 pages; 49 illustrations. 22 x 14 cm. 18s. [£0.9]

Professor Ellis is to be congratulated on the panel of eminent specialists who have contributed to this symposium. The book is intended to counterbalance the "too-exclusive preoccupation with disease in childhood" during medical training, by emphasizing the importance of child health. It is anticipated that it will be of value also in the training of nurses, health visitors and social workers.

The book is divided into two parts: the first deals with the physical, emotional and intellectual development of the normal child, and the second with various social services and conditions relating to child health. The section on development covers various aspects from the ante-natal period to puberty, including antenatal and postnatal care, the development of the foetus, nutrition and feeding, the teeth, growth, intellectual and emotional development, and immunity. The section on social aspects covers genetics, mortality, infant welfare, school health-services, nursery schools, the educational system the care of the homeless, and juvenile courts. One appendix presents an exposition of blood groups and the rhesus series, while another gives a useful annotated list of voluntary organizations concerned with child health. The whole symposium very adequately fills a gap in medical literature and should prove a valuable handbook for doctors, nurses and lay workers.

G. J. H.

### Tuberculosis and Chest Disease for Nurses

G. S. Erwin. London, J. & A. Churchill Ltd., 1946. vii + 236 pages; 39 illustrations. 21 x 14 cm. 10s. 6d. [£0.525]

The title of this book by the Medical Superintendent of the Liverpool Sanatorium, Frodsham, must be read in its literal sense. It is designed to explain in suitable terms the etiology, pathology, diagnosis (both clinical and laboratory), treatment and complications of tuberculosis and of non-tubercular pulmonary disease. It is not a textbook of the nursing technique proper to these conditions but a book which aims at giving the nurse a better theoretical understanding of them, both to increase her own efficiency and to fit her to undertake the work of "a health educator and teacher".

Rather more than half the book is devoted to pulmonary tuberculosis. This section, in addition to the consideration of pulmonary tuberculosis as a disease, gives one chapter to the discussion of various factors such as marriage, pregnancy, age, inheritance and co-existent physical and mental disorders, in relation to pulmonary tuberculosis; a second to a review of the home and institutional managements of the disease; and a third to the public-health aspects of tuberculosis. This last chapter ends with a brief note on the control of tuberculosis amongst nurses themselves.

Part II of the book deals briefly with non-pulmonary tuberculosis and its treatment, medical, surgical and orthopaedic, while part III is devoted to non-tubercular pulmonary disease. In a short appendix the causes of haemoptysis and of pleural effusion are listed.

P. W.

### A Guide to Anatomy for Students of Physiotherapy and Electro-therapy, etc.

E. D. Ewart. Sixth edition. London, H. K. Lewis & Co. Ltd., 1947. xii + 318 pages; 119 illustrations. 22 x 14 cm. £1 5s. [£1.25]

This work, of which the 5th edition was published in 1943, first appeared in 1921, with the express intention of providing a handbook for students preparing for examinations in medical gymnastics and massage. Consideration of body-structures is therefore limited by the special needs of that section of students to which the book is addressed.

It is divided into five sections: osteology, the trunk, head and neck, upper limb and lower limb. The last four sections are preceded by a short introductory chapter in which the general structure of body parts is considered, and each section ends with notes on surface markings.

The new nomenclature has been introduced in this edition, and the illustrations, with which the book is generously provided, have been largely revised.

An appendix gives anatomical questions recently set in the examinations of the Chartered Society of Physiotherapy, of the Association of Occupational Therapists and of the Society of Radiographers. The book is attractively laid out and has a useful index.

P. W.

### Gardiner's Handbook of Skin Diseases

[F.] Gardiner. Fifth edition revised by John Kinnear. Edinburgh, E. & S. Livingstone Ltd., 1948. xv + 250 pages; 80 figures; 20 plates. 19 x 13 cm. 15s. [£0.75]

This useful little book is intended as a handbook for students, general practitioners and nurses and, as such, attempts to deal adequately with the common skin diseases and briefly with the rarer ones. The long interval since the appearance of the previous edition in 1939 has made extensive revision necessary and the whole book has been brought up to date in the light of recent advances, particularly on the therapeutic side. It now includes the most modern methods of treatment, such as BAL in exfoliative dermatitis, penicillin in staphylococcal infections, and sulphapyridine in dermatitis herpetiformis. The illustrations, in particular the coloured plates, are extremely good and are in keeping with the general quality of the production.

G. J. H.

### Current Therapies of Personality Disorders: the Proceedings of the Thirty-fourth Annual Meeting of the American Psychopathological Association, held in New York City, April, 1945

Edited by Bernard Glueck. London, William Heinemann Medical Books Ltd., 1946. 296 pages. 24 x 16 cm. 17s. 6d. [£0.875]

It was a happy idea to publish these Proceedings of the American Psychopathological Association. The Presidential Address contains some thought-provoking quotations, including one from the undelivered last speech of the late President Roosevelt: "Today we are faced with the pre-eminent fact that if civilization is to survive, we must cultivate the science of human relationships . . . which last phrase, Dr. Glueck suggests, might be regarded as being particularly addressed to psychiatrists."

There is an interesting paper by Elsie B. Kris on the use of electro-shock therapy at the Pilgrim

State Hospital. She starts her treatment with a rather higher voltage (90-100 volts) than that used in Britain but finds like the British that a much higher voltage is rarely necessary. Her statement that "Patients with marked hypertension have been found to stand a full course of treatment without any kind of embarrassment" is surprising, as patients with hypertension are regarded as unsuitable for this form of therapy by some doctors. This paper should be read in conjunction with two others: Pharmacological Therapies in Psychiatric Practice, and Public Health Aspects of Insulin and Other Shock Therapies. The three together form a useful review of the development and practice of shock therapy.

Many will agree with Professor T. V. Moore that in dealing with the problem child: "It is not necessary to scold and condemn in order to alter conduct. One waits and leads. There is no necessity of giving advice when advice will not be accepted." His attempts to develop the character of adolescents through the reading of suitable books should command attention. He claims that his treatment is of special value in the behaviour disorders of preadolescent and adolescent children.

Like most works of a composite character not all the papers have the same value, but most of them will repay careful reading and the whole work reflects a refreshingly practical outlook.

F. T.

### Pharmacology and Therapeutics

Originally written by Arthur R. Cushny. 13th edition by Arthur Grollman & Donald Slaughter. London, J. & A. Churchill Ltd., 1947. 868 pages; 74 illustrations. 23 x 14 cm. £2 5s. [£2.25]

Since the last edition of this book in 1940, one of the two former editors has died and the other resigned, so that this edition is in new hands. The new editors have had therefore the difficult task of incorporating the changes necessitated by the notable advances in this subject during the last seven years, and of preserving the character of the original work. They appear to have been successful in both aspects. The bias of this book is in favour of practical therapeutics, so some of the older material of a more experimental nature has been omitted from this edition. It is intended as a textbook rather than a compendium of pharmacological knowledge. Although an American work, it caters for the British reader by giving the British nomenclature as well as the American, in cases where practice in the two countries differs; it also lists *British Pharmacopoeia* preparations as well as those of *The Pharmacopoeia of the United States*. References are confined to those of a pioneer nature and to those which themselves include extensive bibliographies.

G. J. H.

### Hey Groves' Synopsis of Surgery

Edited by Cecil P. G. Wakeley. Thirteenth edition. Bristol, John Wright & Sons Ltd., 1947. viii + 637 pages. 19 x 13 cm. £1 5s. [£1.25]

During the 40 years that have elapsed since the first appearance of this book, many thousands of students must have carried it about with them in the wards and out-patient departments, as did the present editor, Sir Cecil Wakeley. The concise manner in which the whole range of surgical knowledge is presented is the key to its popularity, which has been sustained by the constant revision to which it has been subjected in each edition. Since the previous edition, two years have passed in which advances have been made in many branches

of surgery, and this edition has been thoroughly revised to include them. The sulphonamide group of drugs and penicillin now play a large part in surgical treatment; they are covered in this book not only in the sections dealing with the treatment of acute infections but also in a new chapter on chemotherapy. The numerous line-drawings add to its value as a teaching instrument, and the excellent index makes quick reference an easy matter.

G. J. H.

### Diseases of the Nose, Throat and Ear. A Handbook for Students and Practitioners

I. Simson Hall. Fourth edition. Edinburgh, E. & S. Livingstone Ltd., 1948. xii + 463 pages; 62 figures; 8 plates. 19 x 12 cm. 15s. [£0.75]

The format of the 4th edition of this useful guide remains essentially the same as that of the last one, in 1944. The most outstanding advances in otology of recent years are discussed, among them the use of the fenestration operation in otosclerosis, and the author has incorporated alterations in treatment that have become general since the introduction of penicillin.

H. C.

### Experimental Physiology for Medical Students

D. T. Harris. Fourth edition. London, J. & A. Churchill Ltd., 1947. xi + 299 pages; 257 figures; 1 plate. 26 x 16 cm. 18s. [£0.9]

The divergent techniques available for the performance of many laboratory exercises, and the fact that teachers tend to emphasize different aspects of the subject, do not facilitate the preparation of a generally satisfactory textbook of experimental physiology. Professor Harris has made a praiseworthy effort to cope with these difficulties in the 4th edition of his *Experimental physiology*, which sets forth clearly and concisely the usual class exercises for students for the second M.B. examination, with enough scope in methods and sufficient detail in description to satisfy the requirements of all laboratories. The exercises amply fulfil the needs of M.B. students or of students working for a pass B.Sc. degree, although too advanced for a conjoint student and just falling short of the requirements of the Honours B.Sc. student. Professor Harris' book shows clearly the effect of the trend, now operative over twenty years, to include mammalian and especially human experiments. Many of these are necessarily demonstrations. The electronic devices and schematic presentation of circuits may not be as intelligible to the present-day students as Professor Harris believes, but they serve the useful purpose of focussing attention on the practical advantages of such understanding. This textbook is a most valuable asset to any physiological laboratory.

E. F. McCarthy

### Insect Pests

W. Clunie Harvey & Harry Hill. Second edition. London, H. K. Lewis & Co. Ltd., 1947. xi + 347 pages; 27 figures. 19 x 13 cm. 14s. [£0.7]

This handbook was presumably written for the assistance of sanitary inspectors and other health officials of local authority health-departments. The authors have clearly had much experience in control of domestic insect pests and they give much sound advice on practical procedure and legal responsibility.

This new edition includes a fairly long section containing useful information about the new insecticide DDT. There is also a shorter account of "Gammexane", but this is ambiguous, for it overlooks the importance of basing recommendations on the gamma isomer content. There are some rather unnecessarily full sections on insecticides which have become more or less obsolete or undesirable, especially fumigants such as ortho-dichlorobenzene, heavy naphtha, and formalin.

The biological data are somewhat less satisfactory than the portions devoted to control methods and procedure. Most of the text-figures are very poor and provide little help in identification of the pests. Since the authors consider the scientific names of the insects to be worth including, they would have done well to check the spelling of several of them.

A new chapter is given in this edition devoted (somewhat incongruously) to "mosquitoes and moths" (i.e. clothes moths). This addition should be useful, since local health-departments often receive queries and complaints about these insects.

J. R. Busvine

### Practical Physiological Chemistry

Philip B. Hawk, Bernard L. Oser & William H. Summerson. Twelfth edition. London, J. & A. Churchill Ltd., 1947. xiv + 1323 pages; 329 figures; 5 plates. 23 x 15 cm. £2 10s. [£2.5]

This, the oldest of the American textbooks of physiological chemistry, was first published in 1907; the 11th edition appeared in 1937. Dr. Oser is now a co-author with Dr. Hawk; the third collaborator, Professor Summerson, is associate professor of biochemistry, Cornell University Medical College.

This edition has been largely rewritten and in spite of the exclusion of methods now obsolete or of minor importance, the inclusion of new matter has increased the bulk of the book by approximately a third. This new matter, to quote the preface, includes sections "... on the polarograph; on isotopes; on the sulfa drugs; on metabolic antagonists and antibiotics; on the Warburg tissue-slice procedure; on the theory and practice of photometric analysis; on the electrophoretic fractionation of the plasma proteins; on the composition of foods; and on the various vitamins whose importance has become recognized since the last edition ..."

P. W.

### Biology for Medical Students

C. C. Hentschel & W. R. Ivimey Cook. Fourth edition. London, Longmans, Green & Co., 1947. xii + 752 pages; 453 illustrations. 22 x 14 cm. £1 5s. [£1.25]

This is the 4th edition of a book which first appeared in 1932 and which has seen two new impressions of its 1st edition, two of its 2nd and three of its 3rd. Revision was deferred until the present edition, that is until the new form of the teaching of biology for medical students was settled. As the type for the book was completely destroyed in 1945, the illustrations have had to be redrawn.

The botanical chapters have been entirely rewritten, more space being devoted to plant physiology. Whilst less alteration was needed in those on zoology, a new chapter on bionomics has been included. In the view of the authors the alterations are so extensive that the new edition should be regarded as substantially a new book.

J. L.-J.

### Textbook of Histology for Medical Students

Evelyn E. Hewer. Fourth edition. London, William Heinemann Medical Books Ltd., 1947. viii + 407 pages; 393 figures. 24 x 17 cm. £1 1s. [£1.05]

The 3rd edition of this standard textbook of histology was reviewed in the *British Medical Bulletin*, 1944, 2, 129 (BMB 387/35). In the new edition a 3-page chapter has been added on the protective mechanism of the body: this lists the usual sources of entry of injurious substances into the body, the structures preventing such entry, and the methods by which the body deals with infection or damage to tissues. The author has also enlarged the sections on the reproductive organs and on the respiratory system.

The illustrations are black-and-white photomicrographs and semi-diagrammatic line-drawings. New photomicrographs have been added, and material of academic rather than practical interest deleted, so that the volume has been increased by only about 40 pages.

This textbook covers elementary histology for medical students; references to further work are sparse and lack details.

H. P.

### Food Inspection Notes: a Handbook for Students

H. Hill & E. Dodsworth. Second edition. London, H. K. Lewis & Co. Ltd., 1947. vii + 125 pages. 17 x 11 cm. 6s. [£0.3]

This small handbook, the 1st edition of which appeared in 1943, is prepared by two sanitary inspectors with the purpose of presenting in summarized form present-day knowledge of foods and their inspection, to meet the needs of public-health officials and students. The text of the new edition has been revised, amended where necessary and brought completely up to date. Although the legal aspects of the subject are not dealt with, the book should prove, within its limitations, especially useful to students preparing for examinations.

W. W. S.

### Illustrations of Regional Anatomy

E. B. Jamieson. Seventh edition. Edinburgh, E. & S. Livingstone Ltd., 1947. 320 plates. 21 x 16 cm. (In seven separate sections.) £3 15s. [£3.75]

These illustrations are based on the work of Dr. Jamieson as Demonstrator in the Anatomy Department of Edinburgh University. They were originally diagrams used to illustrate his lectures on regional anatomy, collected and published in book form at the request of undergraduates. Some of the figures are copies of blackboard diagrams, but most of them are the result of observation of actual specimens. In this new edition, in one plate, the original drawing has been altered; in others, alterations, generally in colour, have been made and pointer-legends have been corrected. Explanatory additions have been made in some of the foot-legends of the figures.

H. C.

### The Midwife's Text-Book of the Principles and Practice of Midwifery

R. W. Johnstone. Third edition. London, Adam & Charles Black, 1947. viii + 398 pages; 205 illustrations. 22 x 14 cm. 18s. [£0.9]

Clarity, readability and a high standard of illustration are the hallmarks of this book, of which the 1st edition appeared in 1944 and the 2nd in 1946. There has been a general revision of the text for this edition, and a discussion of nitrous oxide and air analgesia has been added to the chapter devoted to drugs and solutions in common use. A new chapter on the Rh factor and its importance in midwifery has been included.

P. W.

### Supplement to the Catalogue of Lewis's Medical, Scientific and Technical Lending Library: Including a Classified Index of Subjects with the Names of those Authors who have Treated Upon Them. Supplement, 1944-1946

H. K. Lewis. London, Lewis's Library, 1947. iv + 175 pages. 22 x 14 cm. 5s. [£0.25] (To subscribers to the library, 2s. 6d.)

The present supplement is a useful guide to recent accessions to Lewis's Library, and to readers abroad will form an invaluable reference work to medical and scientific books published in Britain and the USA during 1944-46. American volumes are easily identified, as places of publication have been included; moreover, the prices of British works are quoted in sterling. No other single publication contains the same information, and books can be traced otherwise only by tedious search through such serial publications as the *Quarterly Cumulative Index Medicus* book lists or the technical books supplements issued with *Nature*.

F. T.

### An Introduction to Gastro-Enterology. A Clinical Study of the Structure and Functions of the Human Alimentary Tube

James Dunlop Lickley. Bristol, John Wright & Sons Ltd., 1947. viii + 143 pages; 21 illustrations. 19 x 13 cm. 8s. 6d. [£0.425]

This work is, from its length, obviously intended only as a general reminder of some of the problems involved in diagnosis and treatment of gastro-intestinal disorders. It is addressed to senior medical students, younger physicians and medical men returning from the armed forces. It is divided into four parts, on structure, function, abnormal conditions, and practical clinical applications.

D. T. Richnell

### Praktikum der Physiologischen Chemie

H. Lieb. Graz, Jos. A. Kienreich, 1946. 215 pages; 19 figures. 20 x 14 cm.

The author is the Director of the Medico-Chemical Institute of the University of Graz. The book is based on lectures accompanying practical exercises at the Institute and is intended primarily for students. The author has, however, expanded the book by the inclusion of several clinical methods of analysis in the hope that it may also be of use to doctors engaged in clinical work. Each chapter consists of short general remarks on the chemical nature of the substances to be tested, followed by a simple and lucid description of the tests themselves. The more important quantitative methods of analysis are given in an appendix.

W. M. G.

**Nothing New Under the Sun**

J. P. Lockhart-Mummery. London, Andrew Melrose Ltd. [1947] x + 178 pages; illustrations. 22 x 14 cm. 12s. 6d. [£0.625]

The contents of this book, which consists of a collection of essays, are aptly summed up by its title and by the Herrick quotation at the beginning of the preface—"Nothing is new; we walk where others went." In many of his essays, which have arresting titles, the author demonstrates that man, being an essentially imitative animal, has observed and exploited the phenomena of Nature for his own purposes.

The essays are not confined solely to medical subjects, but diverge widely, ranging from an account of the skill in the art of advertisement exhibited in the animal and vegetable kingdoms in relation to our own familiar commercial boostings, to a description of the force of the eruption of Krakatoa, as compared with the too well-known atomic-bomb explosions in Hiroshima, Nagasaki and the Bikini Atoll.

Such subjects as abnormalities of growth, diet and allergy are encountered in essays of medical interest. There are also references to quacks and charlatans, among them being Cagliostro, and Graham of the "celestial bed" fame. History is represented by, amongst other things, a description of water-supply through the ages, and an account of the development of architecture, from primitive hut-dwellings to the use of ferro-concrete and steel girders in modern building construction. The last essay, called *Science on Trial*, is an attempt to assess dispassionately the effect of man's application of scientific discovery, with its potentialities for good and evil, on economic and social structure of the past, present and future.

*Nothing new under the sun* is written throughout in a simple, unconventional style, and as the author says in the preface, is intended to afford interest and amusement to its readers, whose enjoyment will no doubt be increased by William Wood's delightful illustrations.

S. M. S.

**Spanish-English Medical Dictionary**

Maurice McElligott. London, H. K. Lewis & Co. Ltd., 1946. viii + 250 pages. 17 x 11 cm. 12s. 6d. [£0.625]

It is apparent that the compiler of this small dictionary has taken considerable trouble to ensure the accuracy of the 14,000 Spanish words listed and their English equivalents. He has, however, omitted to include a great many of the less ordinary terms and these lacunae seriously impair its usefulness, especially to translators. The author asks in his preface that users should inform him of omissions which they may observe, and which he hopes to include in future editions. The value of the dictionary would be further increased if explanations and examples of the use of words listed were given. It would nevertheless prove useful to those who use the dictionary in conjunction with works of reference, or in order to check spellings. The orthography of the English equivalents is that of *The Oxford English Dictionary*. It is hoped to follow up this dictionary with a companion volume of English-Spanish medical terms.

V. E. C. M.

**Practical Food Inspection. Volume I. Meat Inspection**

C. R. A. Martin. Third edition. London, H. K. Lewis & Co. Ltd., 1947. vii + 316 pages; 138 figures. 22 x 14 cm. 18s. [£0.9]

Intending sanitary inspectors will welcome a new edition of "Martin", but it could be read with

profit by others, particularly medical officers of health. Medical men will probably find the chapters on such diseases as tuberculosis, which occur in both animals and man, of greatest interest.

The work is eminently practical and a mine of information on how to arrive at a "diagnosis" in doubtful cases, e.g., anthrax. A "judgment" is appended to the description of each disease and is particularly useful in such a condition as hydatid cyst, where the destruction of the carcass is not practised as a routine. As the practical nature of the book is stressed it is rather surprising to find no reference to "lumpy jaw" as a synonym for actinomycosis of the jaw bones, either in the text or in the helpful glossary of terms.

The author has illustrated his work with line drawings, but some of these might be omitted, e.g., fig. 71, *Tubercle bacilli*. It would increase the value of the book to public-health workers if the various Acts and Memoranda referred to in the text were included in the index, somewhat after the style of *Clay's Sanitary Inspector's handbook*.

In conclusion, the author presents what at first sight is a dull subject in an interesting manner.

F. T.

**Panchito y el Mosco Anopheles**

México. Secretaría de Salubridad y Asistencia, Dirección General de Educación Higiénica, México, Secretaría de Salubridad y Asistencia, Dirección General de Educación Higiénica. 7 pages; 6 illustrations. 19 x 15 cm.

This booklet explains to children in a very simple and pleasant way the dangers of malaria, its symptoms and signs, the advisability of consulting the doctor in the early stages, the measures to be taken to protect oneself against mosquitoes—in short, it gives a broad outline of the disease and the remedy. The illustrations are good, both amusing and convincing. Any propaganda directed to children has a repercussion in home life, especially in that of poor peasants who were themselves unable to attend school in their childhood, and who regard their children as a source of wisdom and hope and wish to give them a better chance of life than they had themselves. This booklet probably aims at such results and is a good example of indirect propaganda.

M. V. L.

**The Essentials of Materia Medica, Pharmacology and Therapeutics**

R. H. Micks. Fourth edition. London, J. & A. Churchill Ltd., 1947. x + 399 pages. 21 x 14 cm. 18s. [£0.9]

"Micks" is probably the most popular, and certainly the most readable of the smaller books on its subject. The present edition has been extensively revised, and all the more familiar newer preparations that one would expect to find have their place. Yet a proper balance is maintained throughout the work. Penicillin occupies nearly a chapter, for example, but streptomycin is dealt with in a few restrained paragraphs as befits a drug whose proper value is not yet known. Special attention has been directed to anaesthetic drugs, and the section on curare alkaloids is adequate. Thiouracil, and its place in the treatment of hyperthyroidism, forms a useful introduction to the use of this drug. One notes with satisfaction that calciferol is discussed in connection with lupus.

It is sometimes said of the present work that it does not contain enough or that some drugs are excluded that should be included. This is not the fault of the author. The first words of the title are

"The essentials", and opinions are bound to differ as to what should be included under this heading. To quote from the preface: "Two aims have been kept in sight throughout the revision, the exposition of the principles which govern the action of therapeutically important drugs . . ." Therefore it is no use searching the index for information on drugs only used for diagnostic purposes such as iodoxy or pheniodol, even though these are included in similar books on materia medica.

"Micks" is the best introduction to its subject, though in view of what has already been said, prospective examinees should supplement it by reference to other works for some drugs, for example, urethane, which is so useful in the treatment of myeloid leukaemia, but is not to be found in the present edition. The author might consider the inclusion of benadryl in the index when the book is reprinted, especially as it is well described in the text (pp. 188-189).

F. T.

**Gas and Air Analgesia**

R. J. Minnitt. Third edition. London, Baillière, Tindall & Cox, 1947. vii + 80 pages; 19 illustrations. 18 x 12 cm. 5s. [£0.25]

This little work deals with a big subject, the alleviation of the pains of women in labour by the gas-air analgesia of which the author was one of the pioneers. The apparatus and its assembly, and the technique of its use in midwifery, are briefly but adequately described. Contraindications, causes of failure, applications to minor surgery, and statistics and legislative developments complete the scope of the book. No reference is made to any possible psychic after-effects such as have been described by Dr. Helene Deutsch in the USA.

F. T.

**¡ Salud, Madre Campesina !**

Esperanza Peña Monterrubio. México, Imprenta "GAMMA", 1941. 21 pages; illustrations. 23 x 21 cm.

In the rural areas of Mexico, whose population seems to be the audience aimed at by the present author, analphabetism is only one of many minor evils. It has long been recognized by experts on social and health propaganda that in such instances posters and illustrations are the best way to convey ideas of behaviour to men and women unable to understand the written word. The author has grasped very aptly the love of music of the Mexican countryfolk and has included in this booklet the music of a local tune to which a not very happy litany of health rules is to be sung. The illustrations are not convincing, there being no action explained in any of them except in perhaps two cases: the lazy drunken youth and the hard-working teetotaler. As for the text, although it is advisedly written in very plain and direct language to suit the level of intelligence ascribed to the intended readers, we fail to see why it should be so ungrammatical in a supposedly educational booklet.

In the text, a mother gives advice to her growing daughter concerning both her sexual life, and the dangers of alcoholism and venereal disease in her future husband, which might mar the happiness of their children. She also suggests ways to alleviate the primitive conditions of life in their mud-built dwellings ("jacalitos")—the sad scarcity of water, the absence of drainage or sanitation, in short, some of the many misfortunes associated with a poverty-stricken rural area anywhere in the world.

No official authority seems to have sponsored the publication of this booklet.

M. V. L.

**Good Health with Diabetes**

Ian Murray & Margaret B. Muir. Edinburgh, E. & S. Livingstone Ltd., 1947. vii + 40 pages. 18 x 12 cm. 2s. [£0.1]

The purpose of the authors (Physician and Sister-Dietician, Victoria Infirmary, Glasgow) is to provide in the briefest possible form the essential information required by the diabetic patient. In content, price, and format the booklet is suitable to place in the hands of patients themselves. Alternatively, it can be used by the physician as a framework for verbal guidance. The diets have been adjusted to present-day possibilities, and this is, perhaps, the justification for the production of a new work in a field that has already been fairly well covered.

D. T. Richnell

**Epidemia Regional de Malaria en la Cuenca del Lago de Maracaibo, 1942-1943. XII Conferencia Sanitaria Panamericana. No. 23**

M. Nieto Caicedo. Caracas, Editorial Grafolit, 1946. xx + 288 pages; illustrations. 24 x 16 cm.

Dr. Nieto Caicedo is attached to the malarialogical division of the Ministry of Health in Venezuela and in this book gives a very full account of the malaria epidemic of 1942-43 in the Lago de Maracaibo district. The first section of the book describes the population of this district, its geographical and climatic characteristics and the distribution of anopheles throughout the area. Section II gives data relating to the epidemic, which lasted for five months and was preceded by exceptionally heavy rainfall. Statistical tables show the numbers of people affected in different towns and districts. Section III relates the anti-epidemic measures adopted, which included the free distribution of quinine tablets, anopheles control, and press and radio educational propaganda. It is hoped that this book will be of interest and use to malarialogists who may be called upon to combat a similar epidemic.

V. E. C. M.

**Old people**

Nuffield Foundation. Report of a Survey Committee on the Problems of Ageing and the Care of Old People, under the Chairmanship of B. Seebahn Rowntree. London, Geoffrey Cumberlege, Oxford University Press, 1947. vii + 202 pages; illustrations. 21 x 14 cm. 3s. 6d. [£0.175]

Though the problem of extreme and unrelieved poverty in old age has largely been met, there remain many hardships of which the available evidence is too often disjointed and scattered. The work of the Nuffield Committee is therefore highly valuable for its collection and presentation of facts. It included in its survey men over 65 and women over 60. It studied their incomes, their living conditions, the institutions provided for their care, their amusements and their possible capacity for work.

The Committee recognized the bardship of loneliness of old age and the evil consequences for old people, living alone, when mentally or physically they may be unfit to care for themselves. It hoped for a solution of the problem in the provision of special homes which should avoid any suggestion of "institutional" atmosphere. Attention was given also to the potential value of old people's clubs. The Committee further gave considerable attention to employment for the aged, not only as a contribution to national prosperity, but as a means of retarding senility. Its recommendations, based on the survey, deserve the closest attention.

A Medical Sub-Committee reported on schemes of research, either begun or projected, into the process

of ageing. It suggested that there should not be any centralization of this work, but that the programme might be co-ordinated by the Medical Sub-Committee or similar body, which would advise on fellowships and grants in support of independent workers or teams of workers attacking special problems.

The report has 15 appendices giving information on present-day provision for the aged, on the conditions of life of certain selected groups and on the form of questions asked by the field-workers in carrying out the survey.

P. W.

**A Synopsis of Hygiene. (Jameson and Parkinson)**

G. S. Parkinson. Ninth edition. London, J. & A. Churchill Ltd., 1947. viii + 791 pages; 16 illustrations. 22 x 14 cm. £1 8s. [£1.4]

The fact that a book has run through many editions is sufficient evidence that it is meeting a need. This is undoubtedly so with "Jameson and Parkinson", which now reaches its 9th edition, for it has established itself as the textbook for students preparing for the Diploma in Public Health. Sir Wilson Jameson and Lt.-Col. Parkinson were for a dozen years in charge of the teaching for this examination at the London School of Hygiene and Tropical Medicine and were thus in the best possible position to know the needs of students. The 1st edition, by Jameson and Marchant, published in 1920, was a slim volume of only 404 pages. In the 2nd (1927) to 6th (1939) editions, by Jameson and Parkinson, it grew steadily to 687 pages, and the further two editions, by Parkinson alone, have brought it up to very nearly twice the size of the 1st. The assistance of Miss Kathleen M. Shaw, which is acknowledged in the prefaces from the 5th edition onwards, now receives full and well-deserved recognition on the title-page.

In this latest edition we miss the section on personal hygiene by Professor G. P. Crowden, which had been a feature of the 4th to 8th editions. Indeed, the subject as such appears to have been dropped from the book altogether and there is no reference to it in the index. About a third of Professor Crowden's chapter, dealing with nutrition, does however now appear in Section IV, though this fact is not mentioned either in the preface or the text. The increase of 72 pages over the previous edition is due to new legislation (Education Act 1944, National Health Service Act 1946, National Insurance Act, 1946); to new topics, such as the insecticide DDT; and to fuller treatment of many topics, e.g., food poisoning, occupational diseases and hygiene, and hospitals. Appendix V, containing the full text of the new rules for the Diploma in Public Health which came into operation on 1 January 1946, is a very handy feature for the student.

References to the literature are not very numerous and statements such as "Gray in 1928 found paratyphoid bacilli in seven out of twenty specimens . . . and Begbie and Gibson in 1930 found the same organism in seven out of fifty-seven specimens . . ." are occasionally made without any reference at all being given. The method of scattering bibliographic citations throughout the text not only distracts the eye of the reader but makes it very difficult to pick out a particular reference when one is consulting the book for this purpose. When, as happens in many cases, a long string of references is given at once, it is not always clear which author belongs to which title, etc. These are minor faults, but attention to them in future editions would ease the task of those who use this book as a work of reference.

Cyril C. Barnard

**Blood Pressure and its Disorders Including Angina Pectoris**

John Plesch. Second edition. London, Ballière, Tindall & Cox, 1947. xiv + 307 pages; 125 illustrations. 22 x 14 cm. £1 1s. [£1.05]

The author starts out with the most laudable intentions, namely, to restrict "the scope of the book to those matters of which I have personal experience through research and observation", and to refrain "from 'rehashing' what can be found in any standard work". Bearing these statements in mind, and the fact that he was formerly Professor of Internal Medicine in the University of Berlin, it is not surprising to find that the book has many references to foreign literature, and is written in a dogmatic, yet conversational style. New references and case-histories have been added in this edition, and the author is at his best when describing symptoms. Some readers will think that the importance of rest in angina pectoris is insufficiently stressed, and that overmuch space is given to smoking, in what the author admits is an "unconventional discussion." The diet chart of foods "permitted" in angina makes nostalgic reading in these days of worldwide shortages. There are too few monographs on the subject of blood-pressure disorders, and this one should prove a useful addition to the literature of the subject.

F. I.

**The Rhesus Factor**

G. Fulton Roberts. London, William Heinemann Medical Books Ltd., 1947. vii + 47 pages. 18 x 12 cm. 3s. 6d. [£0.175]

The development of research on blood transfusion, stimulated by the discovery of the rhesus factor in 1939 and by the Second World War, has led to discoveries of prime importance to all concerned with the diagnosis and treatment of haemolytic disease. It is the purpose of this booklet by Dr. Roberts, Medical Officer to the North-East London Blood Supply Depot, to acquaint the clinician with the elements and less controversial aspects of the subject. The social implications both of blood transfusion and of disease due to the Rh factor are such that the layman is bound to recognize their significance for himself. This account, therefore, may well prove of interest to readers other than medical men.

Dr. Roberts states that he has a propaganda purpose: "Since . . . every test . . . employs some serum from a patient who has at some time been immunised . . . it behoves every clinician to co-operate in obtaining such sera. Nearly all patients who have been sensitised are in a condition to spare 100 c.c. or more of their blood before the antibody titre falls." *Verb. sap.*

D. T. Richnell

**Zählrohrmethoden im medizinischen Forschungslaboratorium**

F. Roeder & R. Reiter. Göttingen, Vandenhoeck & Ruprecht, 1947. 35 pages; 15 illustrations. 21 x 15 cm.

In this booklet of 35 pages the authors intended to set out the elementary principles of the construction and operation of Geiger-Müller counters and of the necessary electronic circuits (amplifiers, quench-circuit, thyatron scaling circuit). It was meant for the use of technicians and assistants in biological and medical laboratories and therefore the emphasis throughout is on practical matters, although the technical details given seem hardly sufficient to enable the uninitiated to construct his

or her own Geiger-counter. There is no mention of the bell-shaped end-window type of counter which is so extensively used both in the USA and in Great Britain, especially in connexion with the biological application of radioactive isotopes. Because of the particular purpose of the booklet one would have liked to be given practical examples of actual radioactive assays also, especially of isotopes with weak energy radiations, and a fuller discussion of problems of sample mounting. The usefulness of this publication seems very limited indeed, compared with some American publications of recent years. Biologists would welcome a concise account of problems of radioactive assay; unfortunately this pamphlet does not fulfil the task of providing sufficient instruction, either practical or theoretical.

G. Popják

### Common Skin Diseases

A. C. Roxburgh. Eighth edition. London, H. K. Lewis & Co. Ltd., 1947. xxi + 497 pages; 213 illustrations; 8 plates. 22 x 14 cm. £1 ls. [£1.05]

The problem of what constitutes a "common" skin disease can never be finally settled, and the author has justifiably added a number of further conditions to his new edition. It has also been brought up to date by the inclusion of recent experiences with sulphonamides, penicillin and DDT in dermatology. Most welcome is the recognition accorded to the promising treatment of lupus vulgaris with calciferol. The chapter on varicose veins, eczema and ulcer has been re-written and new illustrations have been added. Beyond recording these improvements there is no need to commend this invaluable work to the general practitioner. The standard of production is well maintained, and if one wishes for further coloured plates, this is only a tribute to a work that deserves them. The author himself offers his apology for the necessary increase in price.

D. T. Richnell

### The Childbearing Years

G. Scott Russell. Oxford, Blackwell Scientific Publications, 1947. vii + 88 pages; 11 figures. 22 x 14 cm. 7s. 6d. [£0.375]

This book was written by the author because he felt that young women need a book about themselves, which they can read and digest at leisure and in the seclusion of the home, and which can help them to live fuller and more interesting lives. It is written primarily for those between the ages of seventeen and thirty, but the author adds that parents, teachers and others may find it both interesting and of value.

There is no doubt that this book is a valuable addition to the literature dealing with various aspects of reproduction. It differs from many of its predecessors in that it gives much more anatomical detail as well as a good deal of information about various abnormalities which may arise during the childbearing years. For this reason it is not suitable to be put into the hands of every young woman between the ages of seventeen and thirty, but should only be given to those who have the educational background to understand what they read, and in particular, who are able to place the knowledge they acquire of abnormality in its true perspective. The same remarks apply to the use of this book by parents and teachers, although to a less extent.

Provided the limitations of its use are thoroughly understood this book can be recommended.

J. M. M.

### Cerebro-Spinal Fever. Report by the Infectious Diseases Sub-Committee of the Scientific Advisory Committee, on a Comparison of Penicillin and Sulphonamide Treatment of Meningococcal Meningitis in Young Children

Department of Health for Scotland. Edinburgh, His Majesty's Stationery Office, 1947. 13 pages. 24 x 15 cm. 4d. [£0.0167]

The Scientific Advisory Committee of the Department of Health for Scotland has now produced a second report on the treatment of meningococcal meningitis, supplementary to that published in 1944. It compares the results of penicillin and sulphonamide treatments given alternately, as far as possible to children under 5 years of age. The treatment was carried out in five large hospitals for infectious diseases. The dosage schedule for sulphathiazole (or other active sulphonamide) was similar to that recommended in War Memorandum No. 10 of the Medical Research Council. The penicillin scheme of treatment consisted of 200,000 units systemically on the first day of treatment and 5,000 units intrathecally each day for four days for children under 1 year of age, and double these amounts for children of 1 to 5 years.

The number of cases treated was, unfortunately, too small for statistically significant results to be obtained. Nevertheless, the results exhibit a clear trend in favour of sulphonamide treatment. Although this result was converse to the expectation of the authors it was in line with the impression gained clinically as the trial progressed. The actual figures showed 11 unsuccessful results with penicillin out of 35 treatments, compared with 5 unsuccessful results with sulphonamides out of 31 treatments. When the age distribution of the two groups is taken into account, however, the superiority of sulphonamides is even more apparent, for less than half of the penicillin cases, and as many as two-thirds of the sulphonamide cases, were in the unfavourable age group under 1 year. An additional group of 15 cases, which all recovered, received treatment with both drugs, and although no conclusion can be drawn from this the Committee has embarked on a further investigation of the effects of the combined treatment. Certain minor findings of the report are that sex distribution may be neglected in any comparison of results, that the age-group under 1 year should be separated from that of 1 to 5 years, that the occurrence of complications was a most important factor in determining the outcome, and that the duration of illness before admission, that is, delay in starting hospital treatment, appeared to be a factor in worsening prognosis.

The complications which are enumerated appear to indicate that all the cases under treatment were the "ordinary form" of the disease. It is to be hoped that in future enquiries the Committee will be able to include fulminating septicaemia and other highly fatal forms of the disease, for it is in these that the combination of sulphonamides and penicillin is likely to be most successful.

H. S. B.

### The National Health Service Act, 1946. Being the Complete Text of The National Health Service Act, 1946, with an Introductory Explanation of the Act

J. A. Scott. London, Eyre & Spottiswoode Ltd., 1947. 103 pages. 24 x 15 cm. 5s. 6d. [£0.475]

In the heat generated by the controversy over the operation of the Act this book comes as a cooling

influence. The text itself is available elsewhere, so its value lies in the amplifications, which consist of an index and an introduction. The index, compiled by the Librarian of the Inner Temple, is an expert piece of work and will enable those desiring ready reference to particular points to secure it without wasted effort.

The contribution of Dr. Scott, Lecturer on Hygiene in St. George's Hospital Medical School, is an introduction which sets out in dispassionate terms the steps which brought the Act into being and analyzes its contents. He devotes several pages to the Draft Interim Report of the Medical Planning Commission of the British Medical Association and to the problem of the health centres. He draws attention to the importance of representation of "consumer" interests on administrative bodies, thus emphasizing that patients as well as doctors must have their say. The introduction is only the first word on a subject on which the last will not be written for a very long time, but it enables the reader to see in perspective the aspirations for a greatly improved and comprehensive health-service which have motivated the Act.

D. T. Richnell

### Survey and Field Treatment of Malaria in Mauritius

George Sippe & May Twining. Colony of Mauritius. London, Crown Agents for the Colonies, 1946. v + 76 pages; illustrations. 26 x 16 cm. £1 5s. [£1.25]

Mauritius is an island of 700 square miles<sup>1</sup> and has a population of 400,000, or nearly 600 per square mile. The survey, which was carried out in 1942-43 in response to war-time needs, covers the island in detail. The results show that malaria is hyperendemic in the lowland areas and that figures correspond very closely to those recorded by Ross & Fowler in 1903. Greatest incidence is found below 600 feet<sup>2</sup>; during the summer months; and in Creoles and Hindus, the poorest section of the population. In many villages the splenic index is 100%. The effect of chronic malaria on the splenic rate, parasite-rate, carrier-rate and death-rate is discussed. A clear picture of the relationship of the disease to poverty, malnutrition and macrocytic anaemia emerges. The elimination of mosquito breeding-places is not discussed. "Adequate control" was achieved by atabrin treatment, supplemented by improved nutrition, but whether this can be maintained in peace-time is an unanswered question. The conquest of malaria and the conquest of poverty are clearly shown to be interdependent. The survey is admirably produced, printed on one side of the page, with illuminating charts and photographs.

D. T. Richnell

<sup>1</sup>1 square mile = 2.59 square km.—ED.]

<sup>2</sup>1 foot = 30.5 cm.—ED.]

### Inter-Allied Conferences on War Medicine, 1942-1945: Convened by the Royal Society of Medicine

Edited by Henry Lecheby Tidy. London, Staples Press Ltd. 531 pages; illustrations. 22 x 14 cm. £2 10s. [£2.5]

From December 1942 to July 1945, 24 conferences on war medicine were convened by the Royal Society of Medicine at its headquarters in London. The objects of these conferences were "the interchange and communication of medical experiences in the Field and of the practical application of medicine to the needs of warfare, and for the exposition of the general principles of administration and organization of the medical services." These objects were achieved

by inviting speakers from the allied forces with the necessary technical knowledge and practical experience. For obvious reasons these meetings were secret, and this book now releases some of the valuable and interesting papers presented. The first meeting opened with an account of the abyssinian campaign, and the conferences followed the course of the war through Libya, Tunis, Sicily and Italy and then from D-day to the German concentration camps.

An interesting section is devoted to vivid descriptions by officers of personal experiences in special episodes. Among these are stories by one who volunteered to remain behind at Dunkirk to care for the wounded, by a medical officer parachuted into Yugoslavia, by another who was dropped into Arnhem, the story of the Arctic convoy, and a dramatic description by Professor Richet of 15 months spent in Buchenwald concentration camp. Special subjects, such as malaria, selection of officers and personnel, infective hepatitis and general problems of examination of wounded also received their fair share of discussion. The final meeting was devoted to a review of progress made in war medicine and surgery since 1939 and of the lessons which had been learned. These conferences were held under the presidency of Major-General Sir Henry Letheby Tidy, Consulting Physician to the British Army who, with Dr. J. M. Browne Kutschbach, is responsible for the editing of this volume.

D. F. A.

### Massage and Remedial Exercises in Medical and Surgical Conditions

Noël M. Tidy. Seventh edition. Bristol, John Wright & Sons Ltd., 1947. viii + 480 pages; 190 figures. 22 x 14 cm. £1 5s. [£1.25]

This is now established as a standard textbook for senior students and junior teachers of physical therapy. The material contained makes no claim to originality, and the treatments recommended are drawn from many sources, but the synthesis has proved its worth. The 6th edition was published in 1944; the author states that only slight alterations have now been made, but there is a new description of carbachol ionization treatment in Raynaud's disease.

D. T. Richnell

### An Introduction to Clinical Perimetry

H. M. Traquair. Fifth edition. London, Henry Kimpton, 1946. xv + 330 pages; 255 illustrations. 25 x 19 cm. £1 16s. [£1.8]

This new edition of a standard work is described as "revised and enlarged", but its length and format appear to be almost identical with those of the previous edition. However, it would be mere carping criticism to raise objection to an excellent production on the score of its not being longer. Suffice it that the high level is maintained.

The work has grown with the years from an essay originally written in 1920, and in this edition it has undergone further revision, including changes in the anatomical terminology to "bring it into line with modern usage." It is wholeheartedly to be recommended to ophthalmologists.

D. T. Richnell

### Cirugía

Rafael Urzua. Santiago de Chile, Editorial Tegualda, 1947. 691 pages; 100 illustrations. 23 x 15 cm.

This book is based on lectures delivered by the author to his students in the University of Chile.

It is intended for students and young surgeons, especially men who are starting a career in surgery in remote districts where they cannot obtain advice from more experienced colleagues in emergencies, or consult works in specialist libraries. The author points out, however, that the art of surgery cannot be learnt from books, but only supplemented by them.

Professor Uruza, in his section of general observations, offers much useful advice about the surgeon's attitude to his patients, the physical and mental qualities which he should possess or endeavour to cultivate, and pre-operational preparation. The book is simply written and the various operations are clearly described and illustrated. An appendix gives an alphabetical list of words used in surgical terminology, together with an explanation of their meaning in non-technical language.

V. E. C. M.

### Modern Treatment Year Book 1947 : A Year Book of Diagnosis and Treatment for the General Practitioner

Edited by Cecil Wakeley. London, The Medical Press, 1947. viii + 354 pages; 38 figures. 22 x 14 cm. 15s. [£0.75]

This yearbook, now in its 12th year, has firmly established itself on the bookshelf of the general practitioner as a readable and practical textbook of modern diagnosis and treatment. Under the editorship of Sir Cecil Wakeley, 47 specialists have contributed chapters on a wide range of subjects, including influenza, prematurity, pneumonia, various ophthalmic disorders, hysteria and skin diseases. There is an adequate index.

D. F. A.

### Practical Biology for Medical and Intermediate Students

C. J. Wallis. Second edition. London, William Heinemann Medical Books Ltd., 1947. ix + 396 pages; 211 figures. 22 x 14 cm. £1 1s. [£1.05]

The 1st edition of this book appeared in 1935 and the 2nd has been revised and reset. It covers the syllabi in biology for the First Examinations for Medical Degrees and those of similar content and is intended as a laboratory manual. It is divided into four sections: Microscopical Technique, Elementary Biochemistry, Plant Biology, and Animal Biology, with appendices dealing with the preparation of reagents, biological methods, etc. There is also a list of firms supplying biological apparatus and material.

L. J.

### Practical Pharmacognosy

T. E. Wallis. Fifth edition. London, J. & A. Churchill Ltd., 1948. ix + 230 pages; 73 figures. 22 x 14 cm. 15s. [£0.75]

This work, now in its 5th edition, is supplementary to the author's *Textbook of pharmacognosy* (Churchill, 1946). It describes the practical investigation into the origins and characteristics of crude drugs as well as the means of identification and establishment of criteria of purity.

The first part of the book deals with the practical study of drugs in common usage and consists of a number of schedules of instructions detailing the observations of greatest importance. Short notes with illustrative sketches are included as well as a certain amount of microscopic work, more particularly of those drugs such as starches, hairs, fibres and broken leaves whose characteristics can be studied

only by this means. Guidance in the description of drugs is given, skeleton-reports for the description of plant-members, etc., being included.

The latter and more-advanced half of the book deals with histological and microscopical work. The section on quantitative analysis has been extended by exercises on *nux vomica*, cinnamon and lycopodium. The use of ultra-violet light is given under the schedule for *rubarb* on page 83. The characters of pollen grains as aids to the identification of drugs have been conveniently summarized in a Table and several figures. The histological schedules now include information on the double staining and mounting of botanical sections.

Dr. Wallis is to be congratulated upon this new edition of his manual of practical pharmacognosy. Clearly written, accurately and critically illustrated, it is the standard guide to students reading for qualifications or degrees in pharmacy.

A. Lochter

### A Handbook on Diseases of Children: including Dietetics & the Common Fevers

Bruce Williamson. Fifth edition. Edinburgh, E. & S. Livingstone Ltd., 1947. xii + 408 pages; 87 illustrations. 19 x 12 cm. 15s. [£0.75]

The present edition is well produced like its predecessors; the illustrations are an outstanding feature of the book, which is printed on glossy paper of excellent quality. The book is eminently readable, and is constantly enlivened by reference to the author's own experience. Many readers overseas will find the dosages translated in terms of the metric system one of the most useful features of the work. As stated in the preface, the volume "has been thoroughly revised and incorporates treatment by penicillin and other newer compounds." Thus benadryl is mentioned in connexion with angoneurotic and urticarial conditions.

Rare conditions are mentioned if the author considers them to be important, e.g. chronic constrictive pericarditis, on pages 75-76. The formulae which concludes the book is a most useful feature, though on page 380 only the oral route for the sulphonamides is suggested, and the author does not mention alternative routes if the patient vomits or is unable to swallow. It is true that the intravenous route is indicated in the table on page 381 which is compiled from the Medical Research Council's War Memorandum No. 10 (1943). In the discussion of warts (page 215), no mention is made of plantar warts. But in a work covering such a wide field many readers are bound to regret some omissions, so that such criticisms do not detract from the usefulness of a splendid little book.

F. T.

### Biologists in Search of Material: an Interim Report on the Work of the Pioneer Health Centre, Peckham

Edited by G. Scott Williamson & I. H. Pearce. Second edition. London, Faber and Faber Ltd., 1947. 107 pages; 5 illustrations. 21 x 14 cm. 5s. [£0.25]

This edition has little new to add to that of 1935 for the very good reason that the war greatly interrupted the work of the Centre, but the present day, with its increasing interest in the problem of national health, is an appropriate time for the appearance of a 2nd edition.

The Peckham Centre is not planned solely for regular medical overhaul and general health guidance. It is not an end in itself but a means to an end—the provision of material for a comparative study of the physical processes of health and wellbeing. That it

does not follow the usually accepted pattern of a health- or community-centre is no valid criticism. In spite of considerable pre-war interest, there remained in many minds much vagueness or misconception about the main object of the Peckham Centre. It is good that this object and the methods proposed for its attainment should be set out again for the sake of the stimulus and suggestions of methods which others may find in a study of the Peckham experiment.

### Health Services in England

R. C. Wofinden. Bristol, John Wright & Sons Ltd., 1947. x + 191 pages. 19 x 13 cm. 10s. [£0.5]

Awarded the Joseph Rogers prize in 1946 for "the best or only good essay on the treatment of the sick poor of this country and the preservation of the health of the poor", this lucid little book summarizes measures taken in Great Britain to provide for the treatment of the sick and to preserve the health of all social classes. It reviews the achievements of the health services and concludes with a postscript on the National Health Service Act, 1946, placed on the statute book after the completion of the essay.

H. C.

### A Text-Book of Gynaecology: for Students and Practitioners

James Young. Seventh edition. London, Adam & Charles Black, 1947. xi + 471 pages; 277 illustrations. 22 x 14 cm. £1 10s. [£1.5]

New editions of this textbook for students and practitioners by the London University Professor of Obstetrics and Gynaecology have been appearing regularly since 1921. The 7th contains many additions and revisions, particularly in that ever-developing sphere, sex endocrinology. The section on ovarian tumours has also been expanded. For all its length the book is conveniently compact, being printed on thin paper, on which the illustrations none the less show up well.

D. T. Richnell

## Films

*The four films reviewed in this section have been completed by Imperial Chemical Industries Ltd. and are designed as visual aids to medical instruction. They were shown at the XVII International Physiological Congress in Oxford in July 1947, and are important in that they mark the return to the front rank, after a lapse of some years, of films dealing with physiology and physiological techniques*

1285

### Perfusion of the Living Animal [Dog]

made at Department of Physiology, Edinburgh University; owned by Imperial Chemical Industries Ltd.; technical adviser, Professor I. de Burgh Daly; directed by Cyril Jenkins; unit, Film Producers' Guild; available in 16 mm. sound, 1,600 feet [488 m.]; kodachrome; 34 minutes

For a number of years Professor I. de Burgh Daly and his colleagues in the Department of Physiology at the University of Edinburgh have been engaged in the study of pulmonary vasomotor and bronchomotor activity. The perfusion apparatus which they designed for the unequivocal proof of pulmonary vasomotor activity is demonstrated in this film. It is substantially the same as that described by Daly *et al.* in 1942 (*Quart. J. exp. Physiol.* 31, 227), but with some added refinements; the need for such an elaborate apparatus is well explained in this paper.

In order to ensure that recorded changes in pulmonary arterial pressure were due solely to pulmonary vasomotor nerve stimulation, certain desiderata were also postulated in the same paper. These included a constant systemic arterial pressure; constant inflow of blood to the lungs; constant pressure in both auricles; negative pressure ventilation of the lungs; maintenance of the functional integrity of the pulmonary nerves; separation of bronchomotor from vasomotor effects on pulmonary pressure. It was also desirable that the animal should remain alive during the experiment; that it should not suffer from anoxia at any stage;

that the state of the blood should approach normal; and lastly that the depth of anaesthesia should be under exact control all the time.

The film starts with a general view of the whole apparatus and is followed by one of a model which is rotated so that the essential parts can be seen from all sides. Next follows a diagram of the perfusion circuit which is in two parts, systemic and pulmonary.

Heparinized and filtered blood from several donor dogs flows from the first reservoir to the "systemic" Dale-Schuster pump which replaces the left ventricle. From this pump the blood goes to cannulae in the femoral arteries, thence via the systemic circulation of the whole animal to reach the right auricle. From the right auricular appendix a cannula and tube lead the blood to a second reservoir. The pulmonary circulation is from this reservoir to a second Dale-Schuster pump which passes it by means of a specially shaped cannula through the right ventricle into the pulmonary artery and thus to the lungs. The blood returning to the left auricle is led by a cannula and tube back to the first reservoir, thus completing the circuit. The auricles continue to beat throughout the experiment as their blood supply is intact. In addition to the perfusion circuit already described there is a Hooker-Drinker oxygenator shunted across the reservoirs. In this shunt the blood is exposed to a gas mixture of 95% O<sub>2</sub> and 5% CO<sub>2</sub> which keeps it oxygenated and maintains the pH at 7.2. With this system the respiratory centre may remain active for about eight hours.

The operating table is electrically heated and the reservoirs and Dale-Schuster pumps are immersed in a thermostatically controlled water-bath. For the preliminary stages positive pressure ventilation of the lungs is needed and is supplied by a Starling "Ideal" pump. Later, when negative pressure ventilation, which more nearly approaches normal respiration, is required, a metal chamber is slid over the operating table and fixed in an airtight manner. The chamber is connected to a vacuum pump providing continuous suction. Respiration is controlled by the admission of air to the chamber by a mechanically operated valve.

The tracheal cannula is connected to a closed respiration circuit which includes a soda-lime absorber for CO<sub>2</sub>, a respirometer giving a kymograph record, and provision for the admission of oxygen and for cyclopropane. This anaesthetic is used during the experimental, as opposed to the preliminary operative, period.

The film then shows the various stages of the operation in considerable detail and with great clearness. The dog is anaesthetized, usually with chloralose, and its trachea is exposed, cannulated, and connected to the respiration pump. Great care is taken to secure haemostasis, use being made of diathermic

electrocoagulation for the purpose. The cervical vagosympathetic nerves are exposed and picked up on loose ligatures for stimulation at a later stage.

The heart is exposed and ample time allowed for the firm clotting of any small oozing vessels. This is important, as heparin is given later. The phrenic nerves are crushed to prevent diaphragmatic movements from interfering with tracing recording respiration. The pericardium is opened and the heart supported in a special cradle.

The blood from the donor dogs is equilibrated with the gas mixture; the reservoirs are filled and the pumps started, their outflow cannulae temporarily discharging back into the reservoirs. The femoral arteries are exposed and heparin is given intravenously. A manometer-recording on the kymograph is then connected to a cannula in the left common carotid artery so as to obtain a record of the systemic blood pressure. The femoral artery cannulae are then inserted, though their attached tubes are temporarily clamped and the "systemic" pump turned off.

Special cannulae are inserted into the right and left auricular appendices, connected, as already described, to the reservoirs. The systemic side of the perfusion is now begun by opening the clamps on the tubes leading to the femoral cannulae and starting the systemic pump.

The final stage of the operation is the insertion of a long curved cannula into the pulmonary artery, which is done by making an incision in the tip of the right ventricle and passing the cannula through the heart. It is held in place by strong tapes tied firmly round the whole heart and embracing both ventricles. The pulmonary pump is started and adjusted to give a pressure of 25 mm. Hg which is also recorded on the kymograph.

The operation is now complete and some experiments can be done while the lungs are still working with positive pressure respiration. For example, the addition of 5  $\mu$ g. of adrenalin to the right auricular reservoir causes a temporary rise in blood pressure. The increase in frequency of the auricular beats is beautifully demonstrated in the film by a close-up view of them. Increasing the output of the systemic pump leads to a rise in systemic blood-pressure as shown on the kymograph record. Conversely, stopping this pump causes the pressure to fall and there is a period of apnoea which results as well. The effect of square-wave stimulation of the thoracic nerves is also shown in the film.

The sliding metal chamber is then put in place and the effects of negative pressure ventilation are demonstrated. Observation of the animal is still possible through a glass lid.

The pressure in the pulmonary artery falls owing to a diminution in the resistance of the pulmonary vascular bed. Vagal stimulation, after eserine, leads to bronchoconstriction and a fall in blood pressure due to stimulation of vasodilator fibres. Adrenalin, 5  $\mu$ g., injected into the tube leading to the pulmonary artery, causes a rise in pressure in that vessel. Adrenalin after ergotoxin leads to pulmonary vasodilation as shown by a fall in pulmonary arterial pressure; there is later a fall in the systemic blood pressure.

From this summary it can be seen that the experiments demonstrated are particularly well suited to reveal the presence of the pulmonary vasomotor fibres. The technique will, however, undoubtedly be of considerable value in the elucidation of other problems in the physiology of the cardiovascular and respiratory systems.

The film is beautifully produced and the spoken commentary is a model of lucid expression. It should serve as an example of all that a film, designed to demonstrate both an operative technique and physiological phenomena, should be.

A. G. Sanders

1286 (with 1287)

## The Humoral Transmission of Sympathetic Impulses

made at Department of Pharmacology, Oxford University, 1947; owned by Imperial Chemical Industries Ltd.; technical adviser, Professor J. H. Burn; directed by Cyril Jenkins; unit, Film Producers' Guild; distributed by Imperial Chemical Industries Ltd.; available only in 16 mm. sound, 700 feet [213 m.]; kodachrome; 14 minutes

1287

## The Properties of Acetylcholine

made at Department of Pharmacology, Oxford University, 1947; owned by Imperial Chemical Industries Ltd.; technical adviser, Professor J. H. Burn; directed by Cyril Jenkins; unit, Film Producers' Guild; distributed by Imperial Chemical Industries Ltd.; available only in 16 mm. sound, 700 feet [213 m.]; kodachrome; 22 minutes

The first of these films records an experiment designed to show that the contraction of smooth muscle induced by stimulation of its nerve-supply is effected not by an electrical phenomenon, but by the local release of a chemical substance at the nerve-endings. The experiment is designed to prove is first that the nerve-supply to a smooth muscle is stimulated; if then a chemical substance is released it should be detectable by the contraction produced in a distant smooth muscle whose nerve-supply has been interrupted.

The superior cervical ganglion in a cat is removed on one side, and an injection of adrenalin given. The response of the nictitating membranes, to which lever-and-pulley recorders have been attached, is seen on the kymograph: the operated side shows a greater response, thus exhibiting an increased sensitivity over the normal. Next the splanchnic nerves are divided and stimulated: this produces a negligible response on the normal side, but a marked response on the operated side greater even than that produced by the dose of adrenalin. Now the suprarenals are isolated and removed; when the splanchnics are again stimulated the affected side contracts significantly, while at the same time the blood-pressure tracing rises; the normal side shows no response. So it is shown that stimulation of the splanchnic nerve must have released from the gut some such substance as is produced by the adrenal glands.

The pictorial quality and the smooth exposition of this film combine to present clearly and memorably the argument intended. It is, by its subject-content, a specialized film of use only for physiology students, but here it should find routine use in the standard curricula, for it is short enough to be fitted into the normal lecture—indeed, it presents the subject more forcefully and in a shorter time than has been possible hitherto.

The second film—on the properties of acetylcholine—starts with a portrait of Sir Henry Dale, then presents the chemical structure of acetylcholine and next discusses the one-time mystery—why administration of this drug in small doses produces a fall in blood-pressure, but in large doses a rise. Sir Henry Dale's classical investigations are then repeated. In a cat-preparation a small quantity of the drug injected produces a fall in blood-pressure; by repeating the experiment on an isolated limb it can be seen that this fall must be due to arteriolar dilation. A larger dose of the drug produces a sharper fall in blood-pressure, due to superadded inhibition of the heart; this effect soon passes off, but the blood-pressure remains depressed to some extent, due to continuing arteriolar dilation. A similar effect on the heart can be produced by stimulation of the vagus, while the effect of acetylcholine on the isolated heart mimics vagal stimulations in the intact preparation. Atropine is an antagonist to acetylcholine. The raising of blood-pressure by high doses of acetylcholine is explained by its stimulant action on the suprarenals. Electrical stimulation of the superior cervical ganglion produces responses in the eye which are exactly repeated when the ganglion is painted with acetylcholine.

Here then we have a number of classical experiments collected in some semblance of order, and clearly presented for students to see. Perhaps there are rather too many items for the film to be used in one continuous length as made here; the lecturer may prefer to use it part by part, or else to discuss the whole subject-content fully before putting on the film as a conclusive summary.

It is interesting to note that these two films, together with the highly specialized "Perfusion of the Living Animal," represent the first physiology films to have been made for a number of years. Physiologists were for many years in the vanguard of film teaching, but during the last decade they have shown a tendency to cede this position to others. These three films put them once more to the fore; they are clear, and free of trimmings, admirably

conceived and executed, and commendably succinct. Not too fast for the audience they are designed for, they resist the temptation to consider side-issues or to loiter over non-essentials. The colour quality is excellent, the commentary (in English) clear, and the kinematic direction scientific and polished. Full use is made of close-up; and kymograph tracings, so often the stumbling-block to smooth pedagogy in these physiological films, are presented clearly and interestingly and are supplemented to the full by the commentary.

1288

## The Physiology of the Kidney

made at University College, London; owned by Imperial Chemical Industries Ltd.; technical advisers, Professor F. R. Winton & Dr. J. Richardson; directed by Cyril Jenkins; unit, Film Producers' Guild; available in 16 mm. sound, 2,000 feet [608 m.]; kodachrome; 45 minutes

This film demonstrates the relationship between renal function and the state of the circulation. It is suitable for medical students, and for revision purposes.

The film begins by showing the gross anatomy of the organ. A model shows the interrelation of the renal blood-vessels and the nephrons at a series of different magnifications. That the formation of urine from the blood takes place in the glomeruli by a process of ultra-filtration is illustrated by several experiments. The preparation used throughout the film is that of a dog anaesthetized with pentobarbitone (nembutal). In the first experiment an intravenous injection of half-strength egg albumin is given. Egg albumin has a molecular weight of 34,000, which is about half that of the plasma albumin. Urine samples are collected before and after the injection and tested for protein. The thick, white precipitate that is formed in the specimens collected after the albumin has been administered proves that this substance is freely excreted by the kidney. The animal next receives an injection of Evans blue, a dye of very high molecular weight, which does not colour the urine, whereas, when phenol red is given, the urine rapidly becomes pink, owing to the excretion of the dye. Phenol red, of course, has a very much smaller molecule than Evans blue. These *in vivo* experiments are followed by one in which the two dyes are put into cellophan tubes and immersed in water. Phenol red diffuses through the cellophan, whereas the Evans blue does not. Collectively, these experiments indicate that the urine issuing from the glomerulus is an ultra-filtrate of the plasma.

The preparation of the animal and the kymograph records are then explained in greater detail. Arterial pressure is recorded by a cannula in the femoral artery, venous pressure by one in the external jugular vein; the urine outflow of the right kidney and the pressure in the left ureter are recorded also. The effects on the excretion of urine of variations in the circulation are next demonstrated. A rise in systemic blood pressure does not cause an increase in the flow of urine, because the renal vascular system compensates for the rise in pressure. The intravenous injection of adrenalin also causes a rise of blood pressure and a slowing of the heart beat. The renal arterioles, however, are also constricted so that the flow of urine stops instead of being increased. The absence of any direct control over the renal blood vessels by the vagus is shown.

Electrical stimulation of the vagus causes a fall in arterial blood pressure which in turn lowers the pressure in the glomerular capillaries and results in a decrease in the output of urine. Stronger stimuli of the vagus cause at first a rise of venous pressure as well as a drop in the arterial pressure and again the output of urine is diminished. After the period of stimulation there is one of over-compensation when these effects are reversed.

The effect of a sudden and severe haemorrhage is next shown. Very little change occurs until about 180 cm.<sup>3</sup> of blood have been withdrawn, corresponding to a loss of about 2 litres in a man. After this amount has been withdrawn, the compensatory mechanism fails and there is a fall of arterial pressure with a slight drop also in the venous pressure. The result on the kidney is a diminution in the flow of urine. Restoration of the blood volume by the intravenous infusion of 200 cm.<sup>3</sup> of physiological saline restores the arterial pressure and also the glomerular filtration pressure. The flow of urine returns to normal and even rises above normal because the dilution of the blood with saline

inhibits the re-absorption of water from the urine as it passes through the renal tubules. Normally in man this re-absorption is very considerable.

Diuretics act in two principal ways, either by an increase in the glomerular filtration rate or by causing a decrease in tubular re-absorption of water. The mode of action of caffeine and of two of the "osmotic" group of diuretics is demonstrated in detail.

The film finishes with a résumé of the effects shown, illustrated by the complete kymograph record.

## Catalogue of Medical Films

compiled by The Royal Society of Medicine and The Scientific Film Association. London, Aslib, 1948. vii + 125 pages. 19 x 15 cm. 7s. 6d. [£0.375] (6s. to members of Aslib and SFA)

Part I. Title list of 800 films viewed. (i) Alphabetical cross-reference; (ii) subject-group index; (iii) numerical cross-reference. Part II. Details of 200 films arranged in numerical order. Appendix: the Scientific Film Association; the Royal Society of Medicine; Aslib.

This is a well-planned and comprehensive catalogue which will be invaluable to the growing number of users of medical films. An increasing amount of interest is being shown in the possibilities of the film as an aid to medical education and the appearance of this catalogue is therefore most welcome. Its compilation was made possible as a result of collaboration between the Royal Society of Medicine and the Medical Committee of the Scientific Film Association, although, since 1946, the Scientific Film Association has continued the work alone.

# Guide to the Journals

## Anaesthesia

2 : October 1947

Spinal analgesia in a metropolitan public hospital, 1937-46. (T. P. Crankshaw & G. Kaye) 127-133

Intravenous anaesthesia. (B. R. M. Johnson) 134-137

Choice of anaesthetic. (G. E. H. Enderby) 138-144

The treatment of pulmonary complications in maxillo-facial injuries. (R. P. W. Shackleton) 145-149

Skin temperature as a clinical aid during anaesthesia. (J. Clutton-Brock) 150-152

3 : January 1948

Controlled respiration by means of special automatic machines as used in Sweden and Denmark. (E. T. Mørch) 4-11

The problem of ischaemia in extremities requiring reconstructive surgery. A preliminary report on the value of repeated interruption of the sympathetic nerve impulses to the part by a local analgesic agent. (J. J. Carroll & H. B. Graves) 12-16

The effect of d-tubocurarine chloride on the heart-lung preparation of the dog. (T. C. Gray & R. A. Gregory) 17-20

Myanesis: a report on seventy-six cases. (R. I. W. Ballantine) 20-25

Anaesthesia in India. (P. H. Blackistoo) 26-28

3 : April 1948

Analysis of replies to a questionnaire on the use of chloroform at the present time. (J. Gillies) 45-52

Experiences with chloroform as an anaesthetic agent. (D. S. Middleton) 53-57

Artificial respiration. (E. A. Pask) 59-66

An analysis of pulmonary complications following anaesthesia and analgesia in 2,064 consecutive cases. (F. Holmes) 67-72

Intracisternal injection of procaine. (R. Woolmer) 73-76

## Annals of Eugenics

14 : October 1947

Situs inversus in one monozygotic twin. (H. F. Helweg-Larsen) 1-8

A pedigree of sex-linked ichthyosis vulgaris. (H. Harris) 9

A new estimate of the linkage between the genes for colour-blindness and haemophilia in man. (J. B. S. Haldane & C. A. B. Smith) 10-31

- A genetical factor in perniosis. (H. Harris) 32-34  
 The dysgenic effect of induced recessive mutations. (J. B. S. Haldane) 35-43  
 Length of human gestation with special reference to prematurity. (M. N. Karn) 44-59  
 Phenylketonuria: data on forty-seven British families. (T. A. Munro) 60-88

## Annals of the Rheumatic Diseases

6 : March 1947

- X-ray appearances in chronic rheumatism. (G. D. Steven) 1-14, 27-35  
 Intestinal extract in rheumatic diseases. (A. Renshaw) 15-26  
 Psychosomatic non-articular rheumatism. (E. P. Edmonds) 36-49

6 : June 1947

- American Rheumatism Association: Proceedings of the reunion meeting.  
 Rheumatic diseases among American soldiers in World War II. (P. S. Hench) 68-73  
 Adult rheumatic fever. (E. P. Engleman) 74-76  
 Epidemic tropical arthritis. (D. C. Crain) 76-80  
 Painful homolateral disability of shoulder and hand with swelling and atrophy of hand. (O. Steinbrocker) 80-84  
 Dynamic posture. (B. Howarth) 85  
 The diagnostic significance of focal cellular accumulations in the skeletal muscles of patients with rheumatoid arthritis. (G. K. de Forest, H. Bunting & W. E. Kenney) 86-87  
 The streptococcus serology of rheumatoid arthritis. (A. D. Wallis) 87-89  
 Cardiac lesions in rheumatoid arthritis. (E. F. Rosenberg, L. F. Bishop, H. Weintraub & P. S. Hench) 90-91  
 Precipitating and predisposing factors in rheumatoid arthritis. (J. O. Finney, E. W. Boland & P. S. Hench) 91-94  
 Rheumatoid spondylitis: a study of 1,035 cases. (H. F. Polley & C. H. Slocumb) 95-98  
 Increased protein content of the cerebrospinal fluid in rheumatoid spondylitis. (E. W. Boland, N. E. Headley & P. S. Hench) 99-100  
 Vitamin C and P in rheumatic fever. (J. F. Rinehart) 100-101  
 Chrysotherapy in rheumatoid arthritis. (C. Ragan & T. L. Tyson) 101-108  
 Prolonged oral administration of penicillin in rheumatoid arthritis. (J. A. Coss, R. H. Boots & M. O. Lipman) 108-109  
 The effect of "the muscle spasm of rheumatoid arthritis." (V. G. M. Kydd) 110-114  
 The effect of atoid spondylitis. (R. T. Smith, E. W. Boland & P. S. Hench) 114-116

6 : September 1947

- Spinal osteoporosis, cause unknown. (H. J. Burrows & G. Graham) 129-145  
 Generalized osteoporosis in old age. (C. M. Kesson, N. Morris & A. McCutcheon) 146-161  
 Review of the literature on acute rheumatism during the years 1939-1945. (C. B. Perry) 162-183  
 "Standard bone": a description of radiographic technique. (Being an appendix to the article on page 1 of the March issue). (G. D. Steven) 184-185

## Annals of the Royal College of Surgeons of England

1 : October 1947

- Physiological responses to wounding. (W. K. Livingston) 173-180  
 Post-operative pulmonary embolism. (R. J. V. Pulvertaft) 181-190  
 The use of d-tubocurarine chloride in anaesthesia. (T. C. Gray) 191-203  
 Operative procedures in polio-myelitis. (M. Forrester-Brown) 204-218

1 : November 1947

- Duodenal ulcer. A comparative survey of the immediate and interim results on two groups of patients: one treated by subtotal gastrectomy, and the other by vagus resection. (A. W. Allen) 235-247  
 Some aspects of bronchiogenic carcinoma. (E. A. Graham) 248-264  
 John Hunter as a psychologist. (A. Keith) 265-271

1 : December 1947

- Hypothyroidism. (F. H. Lahey) 277-298  
 The problems of portal hypertension. (J. R. Learmonth) 299-307  
 Vogue and fashion in abdominal surgery. (C. Wakeley) 308-320

2 : January 1948

- Hormones. (E. C. Dodds) 11-17  
 The pathology of sudden death. (K. Simpson) 18-23  
 Anoxia in anaesthesia. (E. A. Pask) 24-33  
 Gastro-intestinal decompression in the treatment of acute obstructions. (R. Smith) 34-54

2 : February 1948

- On cancer of the breast. (G. Gordon-Taylor) 60-68  
 Congenital atresia of the oesophagus. (R. H. Franklin) 69-79  
 Tumours of striated muscle. (D. F. Cappel) 80-92  
 Surgical tuberculosis of bovine origin. (J. W. S. Blacklock) 93-103

2 : March 1948

- The mandibular joint. (C. Wakeley) 111-120  
 Thoraco-abdominal wounds in modern war. (G. Blackburn) 122-128  
 Bilharziasis and bilharzial cancer of the bladder. (H. Ibrahim) 129-141  
 The blood supply of the synovial membrane and intra-articular structures. (D. V. Davies & D. A. W. Edwards) 142-156

## Annals of Tropical Medicine and Parasitology

41 : September 1947

- Photosensitization of Zebu cattle associated with the administration of pbenanthridinium 1553. (F. R. Bell) 165-172

- Observations on the life-cycle of *Schistosoma mansoni* in the laboratory, with a discussion on the snail vectors of *S. mansoni* and *S. haematobium*. (S. G. Cowper) 173-177  
 Field trials with "Gammexane" as a means of malaria control by adult mosquito destruction in Sierra Leone. I. The effect of "Gammexane" on mosquitoes. (G. Davidson) 178-209  
 Field trials with "Gammexane" as a means of malaria control by adult mosquito destruction in Sierra Leone. II. The effect of treatments of houses with "Gammexane" on the malaria-rate in the inhabitants. (G. Davidson) 210-214  
 The consumption of haemoglobin by malaria parasites. (R. H. Black) 215-217  
 The infection of rats by trypanosomes (*T. rhodesiense*) taken from man early in the disease. (H. Fairbairn) 218-225  
 The excretion of stilbamidine and some related compounds in experimental animals. (J. W. F. Hampton) 226-233  
 Notes on the type-specimens of African Tabanidae (Diptera) described by Mr. H. F. Carter (1912, 1915). (H. Oldroyd) 234-238  
 Notes on the early stages of certain Ethiopian mosquitoes, with some locality records from British West Africa. (P. F. Mattingly) 239-252  
 The period required by *Litomosoides carinii* to reach the infective stage in *Liponyssus bacoti*, and the duration of the mites' infectivity. (D. S. Bertram) 253-261  
 Failure to control *Hypoderma* by the spraying of oviposition sites on cattle with "Gammexane." (K. Unsworth, H. Edwards & D. S. Bertram) 262-265  
 Hermaphrodites of *Schistosoma mansoni*. (H. Vogel) 266-277  
 Acquired paludrine-resistance in *Plasmodium gallinaceum*. I. Development of resistance to paludrine and failure to develop resistance to certain other antimalarials. (J. Williamson & E. M. Lourie) 278-291

41 : December 1947

- Experimental studies of an old strain of *Trypanosoma gambiense*. I. The enhancement of its virulence and the relationship of this phenomenon to the species of polymorphic trypanosomes of Africa. (J. H. Sandground) 293-305  
 Experiments on the relation of haemoglobinuria and anuria with reference to blackwater fever. (J. Dawson & G. M. Findlay) 306-320  
 Malignant disease in Nigeria: an analysis of a thousand tumours. (B. G. T. Elmes & R. B. T. Baldwin) 321-328  
 Experimental malarial infections in Australasian anophelines. (M. J. Mackerras & F. H. S. Roberts) 329-356  
 Observations on onchocerciasis in the Bahr-el-Ghazal province of the Sudan. (R. Kirk) 357-364  
 Seasonal and annual variation in the incidence of trypanosomiasis in game. (F. L. Vanderplank) 365-374  
 Studies on synthetic antimalarial drugs. XIX. The effect of therapeutic courses of paludrine on the relapse-rate of vivax malaria. (W. H. H. Andrews, D. Gall & B. G. Maegraith) 375-379  
 On the control of malaria in Freetown, Sierra Leone. I. *Plasmodium falciparum* and *Anopheles gambiae* in relation to malaria occurring in infants. (G. A. Walton) 380-407

## Archives of Disease in Childhood

22 : September 1947

- A study of burns and scalds in children. (B. Morrison) 129-151, 188-190  
 The excretion of 17-ketosteroids and gonadotrophin in children: normal and abnormal cases. (A. M. Hain) 152-158  
 Some medico-social problems involved in child adoption. (H. P. Tait) 159-161  
 Absorption collapse in primary tuberculous infection in childhood. (S. Graham & J. H. Hutchison) 162-169, 185-187  
 Two cases of Ehlers-Danlos syndrome. (F. L. King-Lewis) 170-171, 191  
 Megalencephaly: a report of two cases. (J. Apley & M. Symons) 172-174, 192  
 Osteomyelitis of the maxilla in infancy. (J. C. Haworth) 175-177, 187

22 : December 1947

- Some clinical aspects of lactation. (H. Waller) 193-199  
 The titratable acidity, pH, ammonia and phosphates in the urines of very young infants. (R. A. McCance & M. A. von Finck) 200-209  
 The interrenal syndrome in childhood. (E. C. Allibone, H. S. Baar & W. H. P. Cant) 210-225  
 Urinalysis in dehydration fever. (J. Thomson) 226-231  
 The Addis count in the prognosis of acute nephritis in childhood. (M. D. Giles) 232-235  
 Gastric dilatation, megacolon, and idiocy in identical twins. (D. S. Fairweather & H. J. L. O'Sullivan) 236-241, 257-258  
 Purpura and intussusception. (H. Wolfsohn) 242-247  
 Tumour of the optic chiasma. (S. N. Javett & E. Samuel) 248-250, 259  
 Hereditary pharyngeal agenesis showing dominant Mendelian characteristics. (N. H. Wells & M. Platt) 251-252, 260  
 Acute bacterial endocarditis with a positive blood culture in a child aged one year. (C. P. Lapage & F. A. Langley) 253-254, 258

23 : March 1948

- The paediatric approach to tonsillectomy. (J. A. Glover) 1-6  
 Further observations on the significance of the blood pyruvic acid level in infancy. (E. C. Allibone) 7-16  
 Puberty growth of boys. (R. W. B. Ellis) 17-26  
 Etiological aspects of gastro-enteritis. Part I. (E. Hinden) 27-32  
 Etiological aspects of gastro-enteritis. Part II. (E. Hinden) 33-39  
 Salicylate therapy in children. (G. F. Maggioni) 40-47  
 The pH of the mouth in the newborn infant. (J. Thomson) 48-49  
 Azotaemia in infancy. (S. A. Doxiadis) 50-55

## Biochemical Journal

41 : 1947

- BAL-INTRAV: a new non-toxic thiol for intravenous injection in arsenical poisoning. (J. F. Danielli, M. Danielli, J. B. Fraser, P. D. Mitchell, L. N. Owen & G. Shaw) 325-333  
 Changes undergone by phenylarsenous acid and phenylarsonic acid in the animal body. (T. B. B. Crawford & G. A. Levy) 333-336

- Studies on the reaction between sodium hypochlorite and proteins. 1. Physico-chemical study of the course of the reaction. (R. W. R. Baker) 337-342
- Antidotal activity of British Anti-Lewisite against compounds of antimony, gold and mercury. (R. H. S. Thompson & V. P. Whittaker) 342-346
- The inhibition of succinoxidase by heavy metals and its reactivation with dithiols. (E. S. G. Barron & G. Kalinsky) 346-351
- The fate of arsenical vesicants in the skin and the effect of BAL (British Anti-Lewisite). A. F. Graham, G. A. Levy & A. C. Chance) 352-357
- British Anti-Lewisite as an antidote for acute mercury poisoning. (L. A. Stocken) 358-360
- A note on the microdetermination of British Anti-Lewisite. (G. H. Spray) 360-361
- Further investigations on the metabolism of 2 : 3-dimercaptopropanol. (G. H. Spray, L. A. Stocken & R. H. S. Thompson) 362-366
- The effect of injected British Anti-Lewisite on urinary sulphur and glucuronic acid fractions. (G. H. Spray) 366-370
- The use of British Anti-Lewisite containing radioactive sulphur for metabolism investigations. (R. A. Peters, G. H. Spray, L. A. Stocken, C. H. Collie, M. A. Grace & G. A. Wheatley) 370-373
- Oxidation of phenol and benzoic acid by some soil bacteria. (W. C. Evans) 373-382
- Amino-acids and proteins in haemoglobin formation. 1. Tryptophan. (K. M. Yeshoda & M. Damodaran) 382-388
- The fermentation of sucrose by *Aerobacter aerogenes*. (G. G. Freeman) 389-398
- The turnover of phosphate in the pineal body compared with that in other parts of the brain. (U. Borell & A. Orström) 398-403
- Antibacterial action of some aromatic amines, amidines, amidoximes, guanidines and diguanides. (A. T. Fuller) 403-408
- The hyaluronidase content of semen. (G. I. M. Swyer) 409-413
- The release of hyaluronidase from spermatozoa. (G. I. M. Swyer) 413-417
- The metabolic conversion of naphthalene to 1 : 2-dihydronaphthalene-1 : 2-diol. (L. Young) 417-422
- An investigation into the chemical estimation of the oestrogens in urine. (A. E. Bender & A. Wilson) 423-425
- The tryptophan-tryptophan reaction. 8. The mode of formation of indole. (E. A. Dawes, J. Dawson & F. C. Hapgood) 426-431
- Studies on alcaptonuria. 1. The estimation of homogentisic acid. (A. Neuberger) 431-438
- Studies on alcaptonuria. 2. Investigations on a case of human alcaptonuria. (A. Neuberger, C. Rimington & J. M. G. Wilson) 438-449
- Studies on alcaptonuria. 3. Experimental alcaptonuria in rats. (A. Neuberger & T. A. Webster) 449-457
- Studies in the biochemistry of micro-organisms. 74. The molecular constitution of geodin and erdin, two chlorine-containing metabolic products of *Aspergillus terreus* Thom. Part 3. Possible structural formulae for geodin and erdin. (C. T. Calam, P. W. Clutterbuck, A. E. Oxford, H. Raistrick & S. Marcus) 458-463
- Studies on antibiotics. 2. Bacteriological activity and possible mode of action of certain non-nitrogenous natural and synthetic antibiotics. (H. Rindcrnecht, J. L. Ward, F. Bergel & A. L. Morrison) 463-469
- The importance of folic acid and unidentified members of the vitamin B complex in the nutrition of certain insects. (G. Fraenkel & M. Blewett) 469-475
- Linoleic acid and arachidonic acid in the metabolism of two insects, *Ephestia kuehniella* (Lep.) and *Tenebrio molitor* (Col.). (G. Fraenkel & M. Blewett) 475-478
- Further observations on the non-fermentability of *D-fructopyranose* by yeast. (A. Gottschalk) 478-480
- Creatine and creatinine excretion in women. (G. A. Maw) 482-486
- Oxidation of glucose, glycerol and acetate by *Staphylococcus aureus*. (D. M. Powelson, P. W. Wilson & R. H. Burris) 486-491
- Stability of haemoglobin and of certain endoenzymic enzymes *in vitro*. (D. Keilin & Y. L. Wang) 491-500
- Activity of the cytochrome system in heart muscle preparations. (D. Keilin & E. F. Hartree) 500-502
- Effect of haematin on the oxidation of succinic acid by tissue preparations. (D. Keilin & E. F. Hartree) 503-506
- The determination of oestrogens in human pregnancy urine. A new method of correcting for the brown colour developed in the Kober reaction by non-oestrogenic substances. (M. F. Stevenson & G. F. Marrian) 507-511
- The influence of *L*-ascorbic acid on the rupture of the benzene ring of *L*-tyrosine consumed in high doses by guinea-pigs. (H. A. Painter & S. S. Zilva) 511-519
- The tautomeric conversion of *p*-hydroxyphenylpyruvic acid. (H. A. Painter & S. S. Zilva) 520-522
- The ultraviolet absorption spectrum of human cerebrospinal fluid. (M. H. Hack) 522-524
- A re-examination of balibut-liver oil. Relation between biological potency and ultraviolet absorption due to vitamin A. (R. A. Morton & A. L. Stubbs) 525-529
- The choice of a chelating agent for inactivating trace metals. 1. A survey of commercially available chelating agents. (A. Albert & W. S. Gledhill) 529-533
- The choice of a chelating agent for inactivating trace metals. 2. Derivatives of oxine (8-hydroxyquinoline). (A. Albert & D. Magrath) 534-545
- The potentiation of the toxicity of some vesicants to the pyruvate oxidase system *in vitro* by certain dithio-compounds. (R. A. Peters & R. W. Wakelin) 545-550
- Observations upon a compound of mustard gas and keratine. (R. A. Peters & R. W. Wakelin) 550-555
- The splitting of some thio-ether linkages by silver salts under mild conditions. (R. A. Peters & R. W. Wakelin) 555-558
- 1 : 2 : 4-fluorodinitrobenzene. (H. G. Cook & B. C. Saunders) 558-559
- The utilization of nicotinamide derivatives and related compounds by mammals, insects and bacteria. (P. Ellinger, G. Fraenkel & M. M. A. Kader) 559-568
- Studies in the biochemistry of micro-organisms. 75. Dehydrocarolic acid, a metabolic product of *Penicillium citrinum* Biourge. (A. Bracken & H. Raistrick) 569-575
- The action of vitamin K in hypervitaminosis A. (S. E. Walker, E. Eyleburg & T. Moore) 575-580
- Flocculation tests with electrophoretically separated serum proteins. (N. F. MacLagan & D. Bunn) 580-586
- A method for the estimation of creatinine. (J. A. Barclay & R. A. Kenney) 586-589
- The identification of lower peptides in complex mixtures. (R. Consden, A. H. Gordon & A. J. P. Martin) 590-596
- Gramicidin S: the sequence of the amino-acid residues. (R. Consden, A. H. Gordon, A. J. P. Martin & R. L. M. Syge) 596-602
- Studies on the polysaccharides of capsulated yeasts. (J. Mager) 603-609
- Determination of pregnanediol in urine for diagnostic purposes. (D. Huber) 609-611
- The mode of action of lipotropic agents. Proof of the *in vitro* incorporation of triethyl- $\beta$ -hydroxyethylammonium hydroxide into the phospholipid molecule. (C. S. McArthur, C. C. Lucas & C. V. Best) 612-618
- The pigment of the malarial parasites *Plasmodium knowlesi* and *Plasmodium gallinaceum*. (C. Rimington, J. D. Fulton & H. Sheinman) 619-622
- Acetylation and deacetylation of the *p*-amino group of sulphonamide drugs in animal tissues. (H. A. Krebs, W. O. Sykes & W. C. Bartley) 622-630
- The mechanism of damage to the bone marrow in systemic poisoning with mustard gas. (D. M. Needham, J. A. Cohen & A. M. Barrett) 631-639
- Precipitation of steroid ketones with digitonin. (G. A. D. Haslewood) 639-640

42 : 1948

Brain

70 : September 1947

- The anatomy of traumatic epilepsy. (W. R. Russell) 255-257
- Diffuse progressive metachromatic leucoencephalopathy: a form of Schilder's disease related to the lipoidoses. (R. M. Norman) 257-259
- Penicillin in suppurative lesions of the brain and meninges. (H. Cairns) 251-261
- Muscle tone and the organization of the motor cortex. (J. F. Bosma & E. Gelhorn) 262-273
- Atypical intracerebral haemorrhage: with special reference to cerebral haematoma. (E. C. O. Jewsbury) 274-283
- The terminal connexions of the olfactory tract in the rabbit. (W. E. Le G. Clark & M. Meyer) 304-328
- On the role of the pyramidal system in wild movements. (F. M. R. Walsley) 329-354

70 : December 1947

- Effects of bladder distension on autonomic mechanisms after spinal injuries. (L. Gattmann & D. Winterbridge) 361-404
- Dysprosody or altered "melody of language". (G. H. Monrad-Krohn) 405-414
- Early traumatic epilepsy. (C. W. M. Whitty) 416-439
- Hallucinations of remembered scenes as an epileptic aura. (P. N. A. C. Watt) 440-449
- Facial apraxia and apraxic dysarthria. (P. W. Nathan) 449-455
- A partial form of familial myotonia. (The family G.) (J. J. & H. Lauwers) 473-485
- The mother-child transmissibility problem in relation to a new method for investigating the nervous system. (D. F. Carr) 486-495
- Sinclair & G. Weddell) 495-506

**British Dental Journal**

83 : 19/9/47

Some observations on acrylic resins. (A. C. Deverell) 115-122  
 Post-war school dentistry. (A. T. Wynne) 122-126

83 : 3/10/47

Tongue space in full denture construction. (E. W. Fish) 137-142  
 Some social aspects of industrial dentistry. (J. Levi) 142-146

83 : 17/10/47

The importance of the vertical dimension in complete dentures. (H. H. Boyle) 159-165  
 The twin-wire arch. (B. R. Townend) 165-170

83 : 7/11/47

The importance of the vertical dimension in complete dentures. (H. H. Boyle) 183-189  
 Inlay technique. (R. W. Lovel) 189-191

83 : 21/11/47

An investigation into the permeability of human enamel using osmotic methods. (H. F. Atkinson) 205-214  
 Impressions gathered during a short visit to the United States. (G. H. Leatherman) 214-216

83 : 5/12/47

Foods and feeding as they affect teeth and their environment. (E. C. Sprawson) 227-235  
 The clinical application of fibrin foam and thrombin in oral surgery. (T. C. Henry) 235-238  
 Caries. (P. Pineus) 239

83 : 19/12/47

The role of dentistry in general medicine and surgery. (H. Stobie) 249-251  
 Acute anterior poliomyelitis and the dental surgeon. (C. A. Tinn) 252-253  
 Some psychological aspects of thumb-sucking. (L. Blumenau) 253-254  
 Some removable appliances. (J. H. Glen) 254-258

84 : 2/1/48

Movements of teeth. (J. G. Turner) 1-9  
 The sub-masseteric space. (G. M. Bransby-Zachary) 10-13

84 : 16/1/48

Further local factors affecting dental caries: the shape and contents of occlusal grooves. (P. Pineus) 25-28  
 Some aspects of malignant disease of the mouth and its treatment. (B. Jolles) 28-32  
 Local authority dental services and the National Health Service. (J. F. Pilbeam) 32-35

84 : 6/2/48

Extra-oral pin control of fragments of fractured mandibles: a systematic review of cases. (N. W. A. Holland) 47-52  
 Tissue changes caused by orthodontic treatment. (H. Frey) 52-56  
 A design for acrylic posterior teeth for full dentures. (T. R. Murphy) 57-59

84 : 20/2/48

Teeth of the Cbe Wong. (C. F. Mummery) 69-72  
 Rudimentary teeth. (J. J. de Vries) 72-76  
 Fixation of acrylic inlays by direct polymerisation. (J. W. McLean) 76-79

84 : 5/3/48

The exposed dentine of lower incisor teeth. (M. A. Rushton) 91-96  
 Fluorosis and nutrition in Morocco. Dental studies in relation to environment. (M. M. Murray & D. C. Wilson) 97-100  
 The dental department at Redbill Hospital, Edgware, as a criterion for the hospital services of the National Health Service. (J. A. Hudson) 100-102

84 : 19/3/48

The permeability of human enamel. II. An investigation employing a method of cataphoresis. (H. F. Atkinson) 113-119  
 A survey of the dental condition of children in day and residential wartime nurseries. (E. M. Knowles) 119-125

**British Heart Journal**

9 : July 1947

Electrocardiographic study of typhoid myocarditis. (F. Mainzer) 145-153  
 Heart-vector and leads. Part II. (H. C. Burger & J. B. van Milaan) 154-160  
 Idiopathic cardiac hypertrophy. (D. G. Vulliamy) 161-166  
 The heart in scleroderma. (T. East & S. Oram) 167-174  
 Testicular teratoma with extensive intracardiac metastases. (R. W. E. Watts) 175-180  
 Ergotamine and apparent coronary insufficiency. (G. Biörck) 181-184  
 Coarctation of the aorta. (M. Campbell & S. Suzman) 185-212  
 Myocardial tuberculosis with paroxysmal ventricular tachycardia. (R. Schnitzer) 213-219

9 : October 1947

Heart murmurs. Part II. (W. Evans) 225-240  
 Repetitive paroxysmal tachycardia. (J. Parkinson & C. Papp) 241-262  
 A case of perforated duodenal ulcer and cardiac infarction. (A. W. Branwood) 263-266  
 Paroxysmal heart block in bundle branch block. (W. Stokes) 267-274

The first heart sound in auricular and ventricular extrasystoles. (P. Conix, R. G. Dambrosi & H. F. Wainford-Thomson) 275-282  
 The prognosis of patent ductus arteriosus. (J. Benn) 283-291  
 Cardiac catheterization in cases of patent interauricular septum, primary pulmonary hypertension, Fallot's tetralogy, and pulmonary stenosis. (S. Howarth, J. McMichael & E. P. Sharpey-Schafer) 292-303

**British Journal of Cancer**

1 : June 1947

Changes in cartilage produced by infiltrating carcinoma. (B. Sylvén) 103-109  
 Regional influences in cancer. (D. B. Cruickshank) 109-128  
 Carcinoma of the breast. An analysis of the symptoms, factors affecting prognosis, results of treatment and recurrences in 1,211 cases treated at the Middlesex Hospital. (B. M. Truscott) 129-145  
 The effect of a diet containing yeast upon the development of tumours induced by 2-acetyl-amino-fluorene. (F. Bielschowsky) 146-151  
 Production of mutations in mice by 1:2:5:6-dibenzanthracene. (J. G. Carr) 152-156  
 Carcinogenic constituents of coal-tar. (I. Berenblum & R. Schoental) 157-165  
 On the bearing of time on the neoplastic action of small quantities of  $\alpha$ -estradiol in the endometrium of guinea-pigs. (A. Riesco) 166-172  
 The induction of tumours in mice of the R3 strain by 2-acetylaminofluorene. (L. Foulds) 172-176  
 Forced activation and early detection of the milk-borne agent of mammary adenomas in mice. (B. D. Pullinger) 177-191  
 Arsenical cancer: a review. (O. Neubauer) 192-251

1 : September 1947

On the apparent increase in the incidence of lung cancer in Denmark, 1931-1945. (J. Clemmesen & T. Busk) 253-259  
 A further study of the incidence of cancer of the lung and larynx. (E. L. Kennaway & N. M. Kennaway) 260-298  
 The estimation of tumour susceptibility in pure lines. (C. C. Spicer) 298-310  
 The induction of pulmonary adenomata in mice by urethane. (J. W. Orr) 311-316  
 The histology and histogenesis of pulmonary adenomata of mice. (J. W. Orr) 316-322  
 The control of some factors involved in experimental epidermal carcinogenesis. (G. Calcutt & A. K. Powell) 323-327  
 The influence of 1:2:5:6-dibenzanthracene on the nucleic acid content of the liver of rats maintained on high and low protein diets. (L. A. Elson & R. J. C. Harris) 327-334

1 : December 1947

Cancer of the penis and circumcision in relation to the incubation period of cancer. (E. L. Kennaway) 335-344  
 The frequencies of left- and right-sided breast cancer. (T. Busk & J. Clemmesen) 345-351  
 The skin lesions of monocytic leukaemia. (E. A. Fairburn & A. S. V. Burgin) 352-362  
 Mammary tumours in hybrid mice: a sex-factor in transplantation. (L. Foulds) 362-370  
 Serial transmission of infectious papillomatosis in the domestic rabbit. (F. R. Selbie & R. H. M. Robinson) 371-379  
 The role of croton oil applications, associated with a single painting of a carcinogen, in tumour induction of the mouse's skin. (I. Berenblum & P. Shubik) 379-382  
 A new, quantitative, approach to the study of the stages of chemical carcinogenesis in the mouse's skin. (I. Berenblum & P. Shubik) 383-391  
 Effect of feeding 7OH-2-acetylaminofluorene to albino rats. (C. Hoch-Ligeti) 391-396  
 The histology of pulmonary tumours of the rat induced by 2-acetylaminofluorene. (J. W. Orr & F. Bielschowsky) 396-400  
 Some studies on the action of urethane on mice. (P. N. Cowen) 401-405  
 The course of the metabolism of benzyrene in the skin of the mouse. (F. Weigert, G. Calcutt & A. K. Powell) 405-410  
 The effect of lipid solvents on the rate of elimination and the carcinogenic potency of 3:4-benzpyrene after subcutaneous injection in mice. (H. Weil-Malherbe) 410-422  
 The elimination and carcinogenic potency of 3:4-benzpyrene in mice after subcutaneous injection of non-lipoid solutions. (H. Weil-Malherbe) 423-431

**British Journal of Dermatology and Syphilis**

59 : August-September 1947

The psychological aspects of seborrhoeic dermatitis. (E. Wittkower) 281-293  
 The treatment of sycosis barbae, with special reference to relapses. (B. Russell) 294-300  
 The relation of hair-growth on the body to baldness. (H. Harris) 300-309  
 The assessment of merit of sun-protecting preparations. (W. Koch) 309-312  
 Sclerema neonatorum. (E. Davis & R. T. Brain) 312-314

59 : October 1947

The biochemistry of the skin: a review; with particular reference to the mucopolysaccharides. (E. M. Watson & R. H. Pearce) 327-333  
 Calciferol treatment of lupus vulgaris. (D. E. Macrae) 333-338  
 The absorptive property of various ointments. (J. Rae) 338-339  
 "Feverfew dermatitis." (A. K. Daniels) 340

59 : November 1947

The production of dermatitis by pyrethrum and attempts to produce a non-irritant extract. (K. A. Lord & C. G. Johnson) 367-375  
 Incontinentia pigmenti. (F. Kalz & E. Mackenzie) 375-378  
 A note on milker's nodes. (H. J. Wallace) 379-380

59 : December 1947

Vitamin A and pityriasis rubra pilaris. With a comment about the genetics. (Z. A. Leitner & E. B. Ford) 407-427  
 The intelligence of men with acne. (E. L. Cohen) 428-429

## 60 : January 1948.

- The effect of nutritional disorders on the skin and mucous membranes as observed in the civilian internment camp, Singapore, during the Japanese occupation of Malaya. (J. V. Landor) 1-9  
 Diffuse mesodermal pigmentation with congenital cranial abnormality. (A. Carleton & R. Biggs) 10-13  
 Skin sensitivity to penicillin preparations. (R. H. Meara) 14-17

## 60 : February 1948

- Vitamin A in Darier's disease. (Z. A. Leitner & T. Moore) 41-50  
 Nodular epithelioma. (J. Piérard & A. Dupont) 50-56  
 Pruritus vulvae from rubber, due to allergic sensitivity to alkali. (G. H. V. Clarke) 57-60  
 An all-British mycological culture medium. (G. I. M. Carlier) 61-63

## British Journal of Experimental Pathology

## 28 : December 1947

- Relation between serum protein and haemoglobin in 324 Indian soldiers. (H. Lehmann) 377-384  
 The development of anthrax following the administration of spores by inhalation. (J. M. Barnes) 385-394  
 Varieties of the agglutination-inhibition reaction with newly-isolated strains of influenza virus. (C. H. Stuart-Harris & M. H. Miller) 394-403  
 Some properties of potato virus X in leaf extracts made in different ways. (F. C. Bawden & E. M. Crook) 403-415  
 Investigation into the production of antibacterial substances by fungi. Preliminary examination of the eighth 100 species, all basidiomycetes. (W. H. Wilkins) 416-417  
 Licheniformin, an antibiotic substance from *Bacillus licheniformis*, active against *Mycobacterium tuberculosis*. (R. K. Callow, R. E. Glover, P. D'A. Hart & G. M. Hills) 418-440  
 Dehydrogenase activity in virus infections. (D. J. Bauer) 440-446

## British Journal of Industrial Medicine

## 4 : July 1947

- A study of portable vibrating tools in relation to the clinical effects which they produce. (J. N. Agate & H. A. Druett) 141-163  
 Effects of climatic extremes. (M. Crichtley) 164-190

## 4 : October 1947

- Observations on the toxic effects of eordite. (J. S. Weiner & M. L. Thomson) 205-215; plate, 230  
 The risk of fluorosis in magnesium foundries. (R. G. Bowler, M. Buckell, J. Garrad, A. B. Hill, D. Hunter, K. M. A. Perry & R. S. F. Schilling) 216-222; plates, 231  
 The experimental production of X-ray shadows in the lungs by inhalation of industrial dusts: I. Iron oxide. (H. E. Harding, J. L. A. Grout & T. A. L. Davies) 223-224; plate, 232  
 Argyro-siderosis of the lungs in silver finisbers. (H. J. Barrie & H. E. Harding) 225-228; plate, 229  
 The solubility or distribution coefficient of trichlorethylene in water, whole blood, and plasma. (J. F. Powell) 233-236  
 Barrier creams and their evaluation. (W. M. Cumming, M. C. Cameron, E. B. Cumming & M. C. Macrauld) 237-241

## 5 : January 1948

- Studies in the incidence of cancer in a factory handling inorganic compounds of arsenic. I. Mortality experience in the factory. (A. B. Hill & E. L. Fanning). II. Clinical and environmental investigations. (K. Perry, R. G. Bowler, H. M. Buckell, H. A. Druett & R. S. F. Schilling) 1-15  
 Some physiological observations on West African coal miners. (W. S. S. Ladell) 16-20  
 Uraemia in methyl bromide poisoning: a case report. (A. J. Benatt & T. R. B. Courtney) 21-25  
 Toxic effects of nitroso-methyl urethane. (F. Wrigley) 26-27

## British Journal of Ophthalmology

## 31 : October 1947

- The treatment of traumatic diplopia. (J. C. Neely) 581-642

## 31 : November 1947

- A consideration of aniridia, with a pedigree. (P. H. Beattie) 649-676  
 Induction of an experimental tumour of the lens. (I. Mann) 676-685  
 Xanthelasmata and autonomic nervous system. A new syndrome. (A. Bakker) 686-689  
 A case of bilateral coloboma of the optic disc. (H. L. Hughes) 689-692  
 A case of pseudo-glaucoma. (J. A. Magnus) 692-696  
 A case of an adenoma arising in a sweat gland of the upper eyelid. (F. Clifton & W. H. Gordon) 697-700  
 An unusual case of symmetrical, bilateral, non-traumatic iris prolapse. (M. L. Nairac) 700-702  
 Contracted socket. The splint method of post-operative control. (F. M. Lyons) 703-709

## 31 : December 1947

- A case of metastatic osteosarcoma in the choroid. (V. T. Lees) 713-716  
 The effects of nitrogen mustard on the permeability of the blood-aqueous humour barrier to Evans blue. An instance of the influence of a lesion in one eye on the susceptibility of the other. (H. Davson & J. P. Quilliam) 717-721  
 Peripheral and central disturbances of the visual fields. An aspect of diophtalmology. (N. A. Stutterheim) 721-730  
 Glaucoma secondary to fibrocystic disease of bone. (J. W. E. Cory) 731-737

- The variations in the system of the trunks of the posterior ciliary arteries. (T. Sndakevitch) 738-760  
 Transplantation of vitreous. A preliminary report. (H. M. Katzin & J. Blum) 760-766  
 Autohaemo-therapy in hordeolosis. (H. J. Stern) 766-769

## 32 : January 1948

- Two unusual sclero-corneal neoplasms. (A. Loewenstein & J. Foster) 1-12  
 Intra-ocular foreign bodies. An account of military cases from the Burma-Assam front. (E. J. Somerset & K. Sen) 13-23  
 Solar retinitis. (E. Rosen) 23-35  
 On results obtained by total conjunctival booding of the cornea for serpigineous ulcer. (A. Kettesy) 36-43  
 Local sulphamide therapy of dendritic ulcer. (H. L. Hughes) 43-46  
 Data on the occurrence of calcification in the eye tissues. (M. Radnó) 47-54  
 Treatment of perforated corneal ulcer by autoplasic scleral transplantation. (S. Larsson) 54-57

## 32 : February 1948

- The surgical treatment of pterygium. (A. D'Ombrian) 65-71  
 The origin of the malignant melanomata. (E. Wolff) 72-82  
 "An oculist in Switzerland". (J. Foster) 83-111  
 Retinal artery occlusion. A report illustrating the pathogenesis of the fundal appearances and the effect of acetyl-choline. (I. C. Michaelson) 111-117

## British Journal of Pharmacology and Chemotherapy

## 2 : December 1947

- The technique of testing chemotherapeutic action on *Plasmodium gallinaceum*. (I. M. Tonkin & F. Hawking) 221-233  
 The toxicity of alkyl fluorophosphonates in man and animals. (B. A. Kilby & M. Kilby) 234-240  
 The mode of action of myanasin. (F. M. Berger) 241-250  
 The use of drug antagonists for the identification and classification of drugs. (H. O. Schild) 251-258  
 The influence of calcium and potassium ions on the toxicity of ouabain. (J. B. E. Baker) 259-267  
 The blocking effect of bis-triethylammonium salts on transmission in the perfused superior cervical ganglion of the cat. (T. C. Chou & F. J. de Elío) 268-270  
 The persistence in the blood stream of some analogues of sulphadimethoxy-pyrimidine. (A. Spinks) 271-278

## 3 : March 1948

- The glucose metabolism of *Plasmodium gallinaceum*, and the action of anti-malarial agents. (P. B. Marshall) 1-7  
 The glucose metabolism of *Trypanosoma evansi* and the action of trypanocides. (P. B. Marshall) 8-14  
 Sulphatrene: a chemotherapeutic agent for tuberculosis: pharmacology and chemotherapy. (G. Brownlee, A. F. Green & M. Woodbine) 15-23  
 The treatment of experimental tuberculosis with sulphatrene. (G. Brownlee & C. R. Kennedy) 29-36  
 The chemotherapeutic action of streptomycin, sulphatrene, and promin in experimental tuberculosis. (G. Brownlee & C. R. Kennedy) 37-43  
 The chemotherapy of amoebiasis. Part I. Introduction and methods of biological assay. (L. G. Goodwin, C. A. Hoare & T. M. Sharp) 44-48  
 The chemotherapy of amoebiasis. Part II. Amines derived formally from emetine. (J. A. Goodson, L. G. Goodwin, J. H. Gorvin, M. D. Goss, K. S. Kirby, J. A. Lock, R. A. Neal, T. M. Sharp & W. Solomon) 49-61  
 The chemotherapy of amoebiasis. Part III. Variants of bis(diamylamino)decane. (J. A. Goodson, L. G. Goodwin, J. H. Gorvin, M. D. Goss, K. S. Kirby, J. A. Lock, R. A. Neal, T. M. Sharp & W. Solomon) 62-71  
 The treatment of "shock" with sodium salt solutions. (H. Cullumbine) 72-74  
 The constitution of photostilbamidine, the irradiation product of stilbamidine. (J. D. Fulton) 75-79  
 The effect of injected solutions on the cell content of the cerebrospinal fluid. (T. H. B. Bedford) 80-83  
 Actions of British Anti-Lewisite (2:3-dimercaptopropazone). (J. D. P. Graham & J. Hood) 84-90

## British Journal of Physical Medicine

## 10 : September-October 1947

- Postage stamps and physical medicine. (N. M. Matheson) 150-152  
 Non-articular rheumatism: "fibrositis." (F. Bach) 152-156  
 Progress in physical medicine under the Emergency Medical Service, 1939-45. (R. S. Woods) 157-162  
 Sickness absence in industry. (D. M. Watson) 143-145  
 Alopecia areata. Ten long-standing cases treated with thorium X and ultra-violet light. (P. J. Feeny) 146-148  
 Rheumatic diseases: a challenge and an opportunity. (H. Cohen) 148-159

## 10 : November-December 1947

- Recent trends in the management of poliomyelitis. (E. C. Elkins & K. G. Wakim) 163-167  
 Acute effects of a hot saturated atmosphere upon the human temperature, heart rate and blood-pressure, as influenced by age. (V. J. Miller & F. B. Moor) 167-171  
 Electrophysiology as applied in physical medicine. (A. L. Watkins) 172-176  
 Preliminary studies on the beating and circulatory effects of micro-waves—"radar". (U. M. Leden, J. F. Harnick, K. G. Wakim & F. H. Krusen) 177-184  
 Some facts to consider in evaluating the treatment of poliomyelitis. (J. A. Toomey) 185-192

## 11 : January-February 1948

- A medical theory of gymnastics. (E. Jokl) 2-7  
 Hospital rehabilitation. (J. P. Campbell) 7-10  
 Physical medicine in the care of the aged and chronic sick. (A. Stoddard) 10-13  
 The recording of sickness absence in industry. A system with the object of determining occupational factors of causation. (F. H. C. Beards) 14-19

## British Journal of Radiology

20 : October 1947

- Micro-arteriography. (A. E. Barclay) 394-404  
 Optimal skin tolerance dose levels. (B. Jolles & R. G. Mitchell) 405-409  
 Some factors in the aetiology of osteochondritis of the spine: a report on two families. (F. H. Kemp & D. C. Wilson) 410-417  
 Tomography of the spine in tuberculous disease. (F. G. Wood & M. C. Wilkinson) 418-422  
 The histological features of vesical leiomyoma and leiomyosarcoma: case report. T. involving bone. (S. F. Oosthuizen & J. Barnetson) 426-432  
 Neuroepithelioma of the stomach. (H. W. Gillespie) 433-435

20 : November 1947

- Carcinoma of the bronchus with especial reference to its treatment by radiotherapy. (L. M. Shorvon) 443-449  
 The inhibition of ribo- and thymo-nucleic acid synthesis in tumour tissue by irradiation with X rays. (B. E. Holmes) 450-453  
 Physical aspects of intracavitary radium treatment of carcinoma of the cervix uteri. Part III. A new applicator. (G. J. Neary) 454-469  
 Melorheostosis and the creeping periostitis form of leontiasis. Report of a case of osteitis in a rib showing apparently a connecting link between these two lesions. (H. R. Sear) 470-473  
 A technique for cerebral angiography. (R. H. Boardman & A. A. Vickers) 474-476  
 A report of six cases of coxa magna following synovitis of the hip joint. (B. McMurray) 477-481  
 Tendinitis of flexor carpi ulnaris. (J. W. Winchester) 482  
 The importance of fluoroscopy in the investigation of sinus tracts of the thorax. (T. R. Riley) 483-484

20 : December 1947

- The biological effects of penetrating radiations. (F. G. Spear) 489-490  
 Carcinoma of the stomach: Symposium.  
 I. A radiologist's point of view. (J. L. A. Grout) 491-501  
 II. Gastroscopy in the diagnosis of gastric cancer. (H. W. Rodgers) 502-504  
 III. Cancer of the stomach: some pathological considerations. (M. J. Stewart) 505-507  
 IV. The surgical aspect of carcinoma of the stomach. (H. Taylor) 507-511  
 V. Irradiation of gastric cancer. (G. C. Fairchild & A. Shorter) 511-522  
 VI. The statistical approach to gastric cancer. (D. Jennings) 522-527  
 The association of achalasia of the cardia with oesophageal carcinoma. (P. Baer & K. Sicher) 528-532

21 : January 1948

- The genetic effects of non-sterilising doses of penetrating radiation. (F. Ellis) 1-4  
 Comparison of the lethal effect of neutrons and gamma rays on mouse tumours (a) by irradiation of grafted tumours *in vivo*, (b) by irradiation of tumour fragments *in vitro*. (L. H. Gray & J. Read) 5-10  
 Dosage estimation and distribution in the radium treatment of carcinoma of the cervix uteri. A new method and its clinical applications. (M. Lederman & L. F. Lamerton) 11-26  
 Carcinoma of the cervix: a discussion on the value and techniques of supplementary X-ray therapy. (J. G. Winternitz) 27-40  
 A note on some biological aspects of the radiotherapeutic treatment of carcinoma of the cervix. (P. C. Koller) 41  
 Cranio-skeletal dysplasia. (N. Hajdu & R. Kauntze) 42-48

21 : February 1948

- Hiatus hernia. (S. C. Shanks) 55-66  
 A case of localised traumatic bone absorption in the skull. (F. G. Nicholas, H. C. Furst & R. Tepper) 67-69  
 The anomalous middle lobe of the left lung. (G. L. Hardmao) 70-71  
 Theories of the biological actions of ionizing radiations. (C. B. Allsopp) 72-74  
 A note on the X-ray absorption coefficients of air at wavelengths less than 1.0 Å. (J. R. Greening) 75-77  
 Construction of an exposure calculator for radiography. (G. D. Steves) 78-89  
 A clerical method for use in X-ray diagnostic departments. (A. A. Vickers) 90-94

21 : March 1948

- The development of radiotherapy: a review of 50 years' progress. (N. S. Finzi) 105-108  
 Mammary cancer. The place of surgery and of radiotherapy in its management. Part I. A study of some of the factors which determine success or failure in treatment. (G. E. Richards) 109-127  
 The preselection and analysis of the results of radiotherapy. (J. W. Bong) 128-138  
 Calcification in suprarenal neoplasms. (E. Samuel) 139-142  
 Stomach in a femoral hernia. (Report of a case.) (P. Cave) 143-145  
 Gastric ulcer of the greater curvature. A report of two cases. (R. J. C. Campbell) 146-147

## British Journal of Social Medicine

1 : July 1947

- The relation of morbidity to age in an army population. (L. Hogben & M. M. Johnstone) 149-181  
 Diets in maternity hospitals. (E. W. H. Cruickshank & C. P. Stewart) 182-196  
 Social service for a medical ward. (I. F. Beck, F. V. Gardner & L. J. Witts) 197-208  
 Risk of jaundice following transfusion with pooled plasma or serum. (L. Hogben) 209-211

1 : October 1947

- Studies on age and wastage in industrial populations. I. Age and incidence. (R. Padley) 213-237  
 School medical inspections, their value and limitations. (I. Gordon) 238-250  
 The medical ethnography of the second world war. (L. Hogben, M. M. Johnstone & D. Mullings) 251-275

## British Journal of Surgery

35 : July 1947

- The Hunterian ideals to-day. (J. Walton) 1-6  
 On malignant tumours of the testicle. (G. Gordon-Taylor & N. R. Wyndham) 6-17  
 Intralobar sequestration of lung associated with an abnormal pulmonary artery. (D. M. Pryce, T. H. Sellors & L. G. Blair) 18-29  
 The cut flexor tendon. Experiences with free grafts and steel wire fixation. (J. B. Kinmonth) 29-36  
 Observations on the treatment of traumatic injuries of peripheral nerves. (S. Sunderland) 36-42  
 Ligation of arteries, with particular reference to carotid occlusion and the circle of Willis. (L. Rogers) 43-50  
 A new operation for the treatment of hydronephrosis in association with a lower polar (or aberrant) artery. (H. H. Stewart) 51-57  
 Duodenal obstruction in the newborn: with a description of four cases. (I. Forshall) 58-69  
 Regeneration after sympathectomy and its effects on Raynaud's disease. (H. A. Haxton) 69-76  
 Chronic ulcer of the stomach and duodenum. A study of the end-results of treatment with reference to the effect of war-time conditions in London. (D. M. Douglas) 76-83  
 Internal supravascular hernia: with report of a case. (R. Miller) 84-85  
 Massive neoplastic embolism. (A. S. Till & E. A. Fairburn) 86-89  
 Spasm as a factor in appendicitis. (W. H. Bowen) 89-91  
 Lymphosarcoma of the bladder: report of a case. (G. E. Moloney) 91-94  
 Idiopathic infarction of the omentum. (M. S. Cagney & G. Milroy) 95-97  
 A case of strangulated internal hernia at the age of 91 in the "fossa iliaco-subfascialis". (J. A. Ross & J. W. A. Duckworth) 97-99  
 Seminoma of the epididymis in a young man. (H. Ibrahim) 99-100  
 William Edward Gallie, Professor of Surgery, University of Toronto. 101-104

35 : October 1947

- Papillomatous disease of the renal pelvis. (J. B. Macalpine) 113-132  
 Bilateral renal papillomata: two cases. (J. B. Macalpine) 132-134  
 A case in which two dissimilar growths, an adenoma (adenocarcinoma) and a papillo-carcinoma, occurred in the same kidney. (J. B. Macalpine) 134-136  
 Papilloma of the renal pelvis in dye workers: two cases, one of which shows bilateral growths. (J. B. Macalpine) 137-140  
 The treatment of bladder cancer. (R. Shackman) 140-146  
 Carcinoma of the ampulla of Vater. (J. Morley) 146-151  
 The use of autogenous grafts for the repair of large gaps in peripheral nerves. (H. J. Seddon) 151-167  
 Histological observations on the repair of nerves by autografts. (W. Holmes) 167-173  
 Cleft palate and the mechanism of speech. (M. C. Oldfield) 173-179  
 Phaeochromocytoma. (J. W. S. Blacklock, J. W. Ferguson, W. S. Mack, J. Shafar & T. Symington) 179-197  
 The thoraco-abdominal wound: some observations on 20 personal cases. (E. G. Tuckwell) 197-201  
 Transplantation of the biceps tendon as a treatment for recurrent dislocation of the elbow. (P. P. Reichenheim) 201-204  
 Note on cranial autoplasty. (H. P. Pickerill) 204-207

35 : January 1948

- Surgery of lumbar intervertebral disk protrusion. A study of principles and results based upon one hundred consecutive cases submitted to operation. (M. A. Falconer, M. McGeorge & A. C. Begg) 225-249  
 The surgical treatment of carcinoma of the hypopharynx and the oesophagus. (H. Wookey) 249-266  
 Gram-negative meningitis following head wounds: with especial reference to infection with coliform bacilli. (W. Lewin) 266-280  
 A review of surgical methods in the treatment of essential hypertension. (A. L. McGregor) 281-297  
 Persistent priapism. (H. Bailey) 298-303  
 Posterior gastro-enterostomy for organic pyloric stenosis: a review of the end-results of 80 cases. (H. Reid & R. Marcus) 304-307  
 Mesenteric cysts. (M. Paul) 308-311  
 Intracranial haemorrhage of unusual aetiology: with a report of two cases. (J. A. Ross & A. McQueen) 311-313  
 Strangulated obturator hernia. (A. M. Desmond & F. Hutter) 318-320

## British Journal of Tuberculosis and Diseases of the Chest

41 : July 1947

- Thoracic neuro-fibroma. (A. L. D'Abreu) 55-59  
 The tuberculin test: a comparison of the Patch test and the Mantoux test in West African natives. (R. B. T. Baldwin) 59-63  
 An unusual case of actinomycosis of the lung and thyroid. (L. M. Shorvon & R. Pearson) 64-68  
 Haematogenously disseminated pulmonary tuberculosis. (R. Greaville-Mathers) 68-70  
 Scrotal pneumocele as a transient complication of artificial pneumoperitoneum. (W. N. Rogers & J. V. Garrett) 70-73

41 : October 1947

- Scapulectomy and thoracoplasty. (A. J. Coello) 75-79  
 Chronic military tuberculosis. (W. N. Rogers) 79-84  
 A case of a large thymic cyst successfully removed from the anterior mediastinum. (J. Smart) 84-88  
 The clinical aspects of sarcoidosis. (C. Cameron) 88-92  
 Observations on sarcoidosis. (C. Hoyle) 92-98

## British Journal of Venereal Diseases

23 : June 1947

- Smear and culture diagnosis in gonorrhoea. (J. W. McLeod) 53-60  
 Serological Wassermann "Problem" cases. (R. Thomson) 61-72

- Notes on the incidence of venereal disease in the Bahamas. (W. P. U. Jackson) 73-76  
 The use of Richardson's modification of the Ministry of Health's standard Wassermann reaction (Harrison-Wyler) as a verification test. (A. C. T. Vaughan) 77-84  
 Synergic action of penicillin and sulphathiazole in gonorrhoea. (E. R. Hargreaves) 85-87  
 A case of transfusion syphilis. (G. O. Mayne) 88-89  
 Relief of lightning pains in tabes dorsalis. (W. Fowler) 90-91

## 23 : September 1947

- The epidemiological control of venereal disease. (W. Dalrymple-Champneys) 101-108  
 The Harris slide test. A microflocculation test for syphilis with cardiollipin antigen. (T. M. Vogelsang) 109-115  
 Behcet's syndrome. (G. W. Csonka) 116-120  
 The effects of syringe-transmitted jaundice on the outcome of the treatment of early syphilis. (R. R. Willcox) 121-123  
 A rapid method of standardization of the sheep-cell suspension used in the Harrison-Wyler Wassermann technique. (I. N. O. Price & A. E. Wilkinson) 124  
 Advertisements on the treatment of venereal diseases in the eighteenth and nineteenth centuries. (A. Fessler & R. S. France) 125-127

## 23 : December 1947

- The control of venereal diseases under the National Health Service. (L. W. Harrison) 145-154  
 The masking or delay in the development of syphilis after penicillin therapy for gonorrhoea. (J. A. L. Leeming) 155-170  
 The problem of default in a venereal diseases clinic. A medico-social analysis of 381 women patients. (W. V. MacFarlane & H. M. Johns) 171-179

## 24 : March 1948

- The treatment of syphilis with penicillin. (J. E. Moore) 1-8  
 The treatment of syphilis with penicillin. (G. L. M. McElligott) 9-10  
 The treatment of syphilis with penicillin. (E. M. Lourie) 11-15  
 Discussion on the penicillin treatment of syphilis. 16-17  
 Penicillin in oil-wax mixtures. (J. R. May) 18-25  
 Some aspects of gonorrhoea in the female—with special reference to infection of the rectum. (C. S. Nicol) 26-37  
 Discussion on gonorrhoea in the female. 37-39

## British Medical Journal

## 2 : 4/10/47

- Air-borne infection. (R. J. V. Pulvertaft) 517-520  
 British anti-lewisite. A report on its use and therapeutic value in arsenical intoxications, from the BAL Conference, Medical Research Council. (R. A. Peters and others) 520-521  
 Manic states in the Far East. (R. F. Tredgold) 522-525  
 Homosexual offences and their relation to psychotherapy. (F. H. Taylor) 525-529  
 Sudden death after intravenous injection of a mercurial diuretic ("neptal"). (A. G. Oetle) 530-532

## 2 : 11/10/47

- Penicillin in neurosyphilis. (C. Worster-Drought) 559-564  
 The modern treatment of neurosyphilis. (F. G. Lescher & H. R. M. Richards) 565-567  
 Primary meningococcal ophthalmia. (F. N. Shuttleworth & J. G. Benstead) 568-569  
 The biochemistry of senescence. (C. P. Stewart) 569-571  
 An apparatus for drainage of a temporary ileostomy. (R. M. T. Walker-Brash) 572  
 Six cases of cardiovascular disorder with peripheral neuritis. (E. Leigh & A. R. Hazelton) 573-574  
 A new Swiss otolaryngological clinic. (E. D. D. Davis) 582-583

## 2 : 18/10/47

- The aetiology and prophylaxis of puerperal sepsis. (J. W. Bigger) 599-603  
 Penicillin and the treatment of infected hands in out-patients. (F. d'Abreu, C. M. Flood & H. B. Hewitt) 603-605  
 Relation of bacterial pyuria to Reiter's syndrome. (G. H. Baines) 605-608  
 Photosensitivity to sunlight from use of prophylactic sulphonamides: its relation to vaccination reactions. (G. Watkinson & B. R. Hillis) 609-611  
 Belladonna poisoning. (M. Hamilton & A. B. Selare) 611-612  
 Suppression of syphilis and precocious tertiarism. (J. Marshall) 612-613  
 Nicotinamide and blood sugar. (J. N. Cumings) 613  
 Transient hemiplegia following injection of sodium morrhuate. (W. S. Gardner) 613

## 2 : 25/10/47

- Aetiology of steatorrhoea. (A. C. Frazer) 641-645  
 Some problems of tropical sprue. (D. A. K. Black & L. P. R. Fourman) 645-647  
 Shock in obstetrics. (W. A. Scott) 647-649  
 Breast-feeding in erythroblastosis foetalis. (I. A. B. Cathie) 650  
 Residual subacute and chronic prostatitis after penicillin and sulphonamide therapy in acute gonorrhoea. (F. C. B. du Coudray) 651-654  
 Thiopentone-nitrous-oxide-oxygen anaesthesia with curare for head and neck surgery. (J. G. Bourne) 654-655

## 2 : 1/11/47

- All the vitamins. (L. J. Harris) 681-684  
 "Q" fever. A serological investigation of a group of cases previously reported as primary atypical pneumonia. (J. E. Caughey & J. A. Dudgeon) 684-685  
 The plasma viscosity in rheumatic diseases. (I. C. Cowan & J. Harkness) 686-688  
 A case of keratoderma punctata. (B. Phillips) 689  
 Vitamin K for the relief of chilblains. (D. P. Wheatley) 689-691  
 Calcium deposits in the iris in a case of secondary hyperparathyroidism. (C. Poniedel) 691-692  
 Babcock's operation for thoracic aneurysm. (F. T. Ranson) 692  
 Centenary of chloroform anaesthesia. (D. Guthrie) 701-703  
 A method of abdominal palpation. (E. W. Price) 703

## 2 : 8/11/47

- The peep-show. A new technique for pure-tone audiometry in young children. (M. R. Dix & C. S. Hallpike) 719-723  
 Social surveys: medical and psychiatric aspects. (C. P. Blacker) 723-726  
 Child-bearing and pulmonary tuberculosis. (C. J. Stewart & F. A. H. Simmonds) 726-729  
 Appendicitis in the young child. (H. Williams) 730-732  
 Endocyme foetus in a Fiji infant. (R. W. D. Maxwell) 732-733  
 Severe anaemia due to diaphragmatic hernia. (N. J. Roussak & S. Eden) 733

## 2 : 15/11/47

- Thionitril in toxic goitre: a review of four years' experience. (H. Cookson & F. H. Staines) 759-762  
 Malnutrition of the nervous system. (W. R. Brain) 763-766  
 Biochemical applications of stable and radioactive isotopes. (A. S. McFarlane) 766-768  
 Diabetes insipidus and uterine atony: a case observed over a period of 26 years. (G. Marañón) 769-771  
 Nephritis in textile workers. (R. Platt) 771-772

## 2 : 22/11/47

- Sherrington's impact on neurophysiology. (J. F. Fulton) 807-810  
 Sherrington—the man. (T. G. Brown) 810-812  
 Sherrington as philosopher. (A. D. Ritchie) 812-813  
 Metabolic disturbances after injury. (J. Beattie) 813-817  
 Synchronous combined total gastrectomy. (J. B. Hume & G. Blackburn) 817-819  
 Effect of penicillin on bacterial flora of the mouth. (D. A. Long) 819-821  
 Calculation of Tuxford's index by graphical methods. (H. Campbell) 821-822  
 Physiology of the cerebral motor cortex: the contribution of clinical study. (F. M. R. Walshe) 830-832  
 A suggested hospital unit. (H. J. McCurrah) 832-834

## 2 : 29/11/47

- The value of B.C.G. vaccination in control of tuberculosis. (G. S. Wilson) 855-859  
 Sympathectomy and intraspinal alcohol injections for relief of pelvic pain. (J. P. Greenhill) 859-862  
 Relief of pain in intractable cancer of the pelvis. (M. Kenny) 862-863  
 Staphylococcal infection due to penicillin-resistant strains. (M. Barber) 863-865  
 Allergy to penicillin, with symptoms of serum sickness. (A. G. Wilkinson & K. Zinnemann) 865-866  
 Chronic battle neurosis treated with leucotomy. (W. Sargent & C. M. Stewart) 866-869  
 The Newcastle-upon-Tyne obstetric emergency service. (F. Stabler) 878-880

## 2 : 6/12/47

- Streptomycin and tuberculous meningitis in children. Preliminary note. (R. Debré, St. Thieffry, E. Brissaud & H. Noufflard) 897-901  
 The tropical lichen planus syndrome. (W. Williams) 901-904  
 Poliomyelitis: a second attack. (M. W. Alves & I. Pugh) 904-905  
 The tetralogy of Fallot and its surgical treatment. (G. Murray) 905-906  
 Complete heart block in young people. (J. R. H. Towers & C. Bremer) 906-908  
 Tonsillectomy and adenoidectomy: unsatisfactory results due to chronic maxillary sinusitis. (F. M. Walker) 908-910  
 Resettlement from a base hospital. (M. J. Mayfield) 919-921

## 2 : 13/12/47

- Prevention of renal damage by use of mixtures of sulphonamides: animal-experimental and clinical studies. (D. Lehr) 943-946  
 Sulphamerazine treatment of pneumonia in adults. (H. Joules & S. D. V. Weller) 947-950  
 Oral penicillin in treatment of pneumonia in the adult. (T. Anderson & J. B. Landsman) 950-953  
 Oral penicillin in young children. (A. I. Suchett-Kaye & R. B. Latter) 953-954  
 "Lymphatic reaction" among relatives of leukaemic patients. (S. N. Ardashnikov) 955-958  
 Production of Rh agglutinins anti-C and anti-E by artificial immunization of volunteer donors. (J. J. Van Lohem) 958-959  
 The dangers of going to bed. (R. A. J. Asher) 967-968

## 2 : 20/12/47

- Experimental investigations of parodontal disease. VI. Further clinical studies of sugar-cane gnawing in treatment of gingival disease. (J. D. King) 987-991  
 Serological diagnosis of epidemic influenza by the complement-fixation reaction. (L. Hoyle & R. W. Fairbrother) 991-994  
 The general practitioner and the influenza problem. (C. H. Stuart-Harris) 994-996  
 Amoebic abscess of the left buttock in a symptomless cyst carrier. (T. C. Morton & S. F. Soutar) 996-997  
 A case of severe pre-eclamptic toxæmia with central placenta prævia. (G. Newbold) 997-998

## 2 : 27/12/47

- Acute poliomyelitis with special reference to early symptomatology and contact histories. (D. McAlpine, P. H. Buxton, M. Kremer & D. J. Cowan) 1019-1023  
 Poliomyelitis: the pre-paralytic stage, and the effect of physical activity on the severity of paralysis. (W. R. Russell) 1023-1028  
 Poliomyelitis and polio-encephalitis: the case for a review of terminology. (L. H. Murray) 1028-1030  
 Differential diagnosis of jaundice by flocculation tests. (J. B. Rennie with technical assistance of S. L. Rae) 1030-1032  
 Paracolon bacillus infection causing cholecystitis and suppurative hepatitis. (K. Walton & J. C. Leedham-Green) 1033  
 Organizing a geriatric department. (L. Cosin) 1044-1046

## 1 : 3/1/48

- Penicillin in subacute bacterial endocarditis. Report to the Medical Research Council on 269 patients treated in 14 centres appointed by the penicillin clinical trials committee. (R. V. Christie) 1-4

Intravenous alimentation. (H. E. Magee) 4-7  
 Rarer manifestations of herpes zoster. (T. Parkinson) 8-10  
 Treatment of chronic ulceration after irradiation of plantar wart. (M. H. Shaw) 11  
 Exertion haemoglobinuria. (E. J. L. Lowbury & A. P. L. Blakely) 12-13  
 "Tridione" in the treatment of petit mal. (A. J. M. Butcher) 13-14

## 1 : 10/1/48

Anaemia associated with trauma and sepsis. (J. Vaughan) 35-39  
 The effect of food supplements on poorly fed workers in Brussels in January, 1945. (G. A. Smart, T. F. Macrae, P. A. Bastenie & P. E. Grégoire) 40-43  
 Viability of strangulated bowel. Interim report of surgical sub-committee of the clinical research committee of the Public Health Department of the London County Council. 43-46  
 Eosinopenia caused by adrenaline infusion and by insulin hypoglycaemia. (Z. Z. Godlowski) 46-48  
 The convulsive properties of thiopentone. (R. L. Wynne) 48-49  
 Granulosa-cell tumour of ovary as acute abdominal emergency. (A. C. Brewer) 49

## 1 : 17/1/48

Streptomycin: a valuable anti-tuberculosis agent. (W. H. Feldman & H. C. Hinshaw) 87-92  
 Cancer of the stomach in Addison's anaemia. (W. A. Bourne) 92-94  
 The complications of mumps. (D. Laurence & D. McGavin) 94-97  
 Fatal air embolism during mastectomy. (C. L. Hewer & H. I. Coombs) 97-99  
 Hypertrophic pyloric stenosis in the adult. (A. Hobson) 99-100  
 Congenital hypertrophic pyloric stenosis. Report of four cases in brothers. (A. A. H. Gailey) 100-101

## 1 : 24/1/48

The training of specialists. The place of postgraduate institutes. (F. Fraser) 135-139  
 Smallpox in Staffordshire, 1947. Outbreak at Bilston. (C. S. Smith) 139-142  
 Absorption of vitamin D in steatorrhoea. (L. P. R. Fourman & G. H. Spray) 142-144  
 Superior mesenteric arterial occlusion. Recovery without resection. (W. G. Hendry) 144-146  
 Chemotherapy of infected urines in paraplegia. (P. T. J. C. P. Warner) 146-148  
 Cardiac murmurs in infancy. (N. Cox) 148-150

## 1 : 31/1/48

Our founders and benefactors. (C. E. Lakin) 185-188  
 The localization of deep pain. (J. B. Harman) 188-192  
 The pre-erythrocytic stage of mammalian malaria. (H. E. Shortt, P. C. C. Garnham & B. Malamos) 192-194  
 The role of trichlorethylene in general anaesthesia. (G. Ostlere) 195-196  
 Homologous serum jaundice. (K. B. Scott & G. H. Tovey) 196-197  
 Homologous serum jaundice in infancy. (J. Apley & H. R. E. Wallis) 197-198

## 1 : 7/2/48

Effects of war on child health. (R. W. B. Ellis) 239-245  
 Observations on rationing in tuberculosis. (R. Y. Keers) 245-247  
 Generalized infection with the virus of herpes simplex. (R. H. Kipping & A. W. Downie) 247-249  
 Effect of thiocyanate on basal blood pressure. (K. S. Alstad) 250-251  
 Treatment of angina pectoris by reduction of basal metabolism. (G. Schoenewald) 251-253  
 Acute hepatitis treated with methionine and choline. (D. G. Cameron & M. L. Newhouse) 253

## 1 : 14/2/48

The aftermath of gastrectomy. (N. C. Lake) 285-288  
 Curare in oil in the treatment of spastic conditions. (C. A. Clarke & R. D. Holston) 289-291  
 Louse-borne relapsing fever in Persia. (R. I. Bodman & I. S. Stewart) 291-293  
 What the medical practitioner wants to know. (R. T. Bevan) 294-296  
 Brodie's abscess of the tibia: its treatment by surgery, penicillin, and sulphadiazine. (S. Scott & F. S. Preston) 296-297

## 1 : 21/2/48

Social medicine in the curriculum. (J. B. Grant) 333-336  
 The problem of chilblains: with a note on their treatment with nicotinic acid. (R. J. Gourlay) 336-339  
 Hypothalamus and pituitary gland: with special reference to the posterior pituitary and labour. (G. W. Harris) 339-342  
 Disorders of the nervous system due to malnutrition. (H. S. Stannus) 342-343  
 An improved direct coagulase test for the rapid detection of staphylococcus aureus. (I. Lominski & E. Grossfeld) 343

## 1 : 28/2/48

Sepsis scientifica. (G. Jefferson) 379-382  
 The bactericidal action of streptomycin. (L. P. Garrod) 382-386  
 Calciferol in the treatment of cutaneous tuberculosis. (G. D. Powell, P. R. Pearsall & J. E. M. Wigley) 386-389  
 Retroperitoneal haemorrhage in pregnancy. (J. K. Ogden) 389-391  
 Clinical value of some methods of estimating erythrocyte sedimentation rate. (J. R. Sinton) 391-393  
 Erythrocyte sedimentation rate. The effect of alcohol as contaminant. (W. O. Sykes) 393-394

## 1 : 6/3/48

Chondromalacia patellae. (C. Gray) 427-430  
 Vitamin D in treatment of cutaneous tuberculosis. (G. B. Dowling, S. Gauvain & D. E. Macrae) 430-435  
 Hypertension—etiology and surgical treatment. (G. Bourne) 435-440  
 Role of sympathetic nerve in cancerous pain: an inquiry on 300 cases. (M. Dargent) 440-442  
 Aseptic necrosis of pancreas due to arterial thrombosis in malignant hypertension. (W. Pagel & A. L. Woolf) 442-443

"Temporal arteritis". Some aspects of subacute arteritis in later life. (G. H. Jennings) 443-447  
 Three cases of synoviomia. (V. C. J. Harris) 447-448  
 Balantidial dysentery: report of a fatal case in Assam. (A. A. Miller & C. R. Peck) 448-449  
 Intrauterine rupture of the umbilical cord. (G. Bancroft-Livingston) 449-451

## 1 : 13/3/48

Where are we going? Medicine in a planned economy. (F. Roberts) 483-485  
 The health of 407 new students. (J. Pemberton) 490-492  
 The recognition of toxicogenic bacterial strains in vitro. (S. D. Elek) 493-495  
 Speransky's method of spinal pumping in rheumatoid arthritis: a review of four cases. (O. Savage) 496-497  
 Diverticulitis presenting as emphysematous cellulitis of leg: clinical report on two cases. (R. L. G. Dawson & R. H. Hardy) 498-499  
 Recurrent renal lithiasis. (A. D. Wright) 499

## 1 : 20/3/48

Epilepsy. (C. Symonds) 533-537  
 A psycho-analytic concept of the origin of depression. (W. C. M. Scott) 538-540  
 The significance of Harrison's grooves. (J. Naish & H. R. E. Wallis) 541-544  
 "Myanecin" as a relaxant in children. (W. H. A. Davison) 544-545  
 Treatment of gold dermatitis by BAL. (N. R. W. Simpsom) 545-546  
 "Amellin" for diabetes. (H. Whittaker) 546-547  
 The pre-erythrocytic stage of human malaria, plasmodium vivax. (H. E. Shortt, P. C. C. Garnham, G. Covell & P. G. Shute) 547

## 1 : 27/3/48

De Formatione Ovi et Pulli. (H. A. Harris) 585-586  
 Environmental factors influencing health and efficiency in warships. (F. P. Ellis) 587-592  
 Permanent homonymous quadrantanopia after migraine. (W. M. Rich) 592-594  
 Pblebothrombosis decubiti and prevention of pulmonary embolism. (H. Bailey) 594-597  
 Treatment of thyrotoxic heart disease by methyl thiouracil. (W. E. Clarke) 597-599  
 Penicillin and gonorrhoea. An analysis of 150 cases treated by the single-injection method. (C. C. R. Downing) 599-601

## Bulletin of Hygiene

## 22 : December 1947

The action of enzymes on antibodies. (M. V. Stack) 733-741

## 23 : February 1948

Avoidable meningitis. Memorandum drawn up by the Public Health Laboratory Service and the London Sector Pathologists' Committee. 79-80

## Clinical Science

## 6 : 1948

Renal function in Addison's disease. (P. H. Sanderson) 197-206  
 Renal failure following abdominal catastrophe and alkalosis. (P. H. Sanderson) 207-222  
 Blood cholestes in normal subjects and in liver disease. (S. Sherlock & V. Walsh) 223-234  
 The intralobular circulation in acute liver injury by carbon tetrachloride. (L. E. Glynn & H. P. Himsworth) 235-245  
 Low blood pressure in diabetic coma. (S. Howarth, J. McMichael & E. P. Sharpey-Schafer) 247-255  
 The estimation of the extracellular fluid volume by the thiocyanate method in children and adults. (S. A. Doxiadis & D. Gairdner) 257-267  
 The action of adrenaline, ephedrine and methedrine on the circulation in man. (W. J. Allen) 269-279  
 The measurement of bone opacity. (E. G. L. Bywaters) 281-287  
 The absorption of xylose in steatorrhoea. (L. P. R. Fourman) 289-294  
 Renal haemodynamics in acute nephritis. (D. A. K. Black, R. Platt, E. N. Rowlands & H. Varley) 295-302  
 Slow recovery from ischaemia in human nerves. (E. D. Barlow & E. E. Pochin) 303-317

## Dental Record

## 67 : August-September 1947

Functional jaw orthopaedics. A symposium by three dental surgeons. Part I. General experiences. (C. L. Endicott) 190-193. Part II. Construction. (V. G. Pedley) 194-199. Part III. Research. (W. Grossman) 199-205  
 Anaesthesia in dentistry. (F. Fraser) 206-212

## 67 : October 1947

Factors concerned in the growth and development of the jaws and teeth. (J. E. Harris) 222-229  
 Principles and construction of the oral screen as a functional appliance. (R. Caseley) 230-235  
 The dental care of children under five years of age. (L. Clisch) 236-240

## 67 : November 1947

Experimental welder design. (G. J. Parfitt & S. Friel) 250-259  
 Acrylic restorations with gold occlusal reinforcement. (C. Levy) 260-262  
 Orthodontics for the masses. (C. F. L. Nord) 263-267

## 67 : December 1947

Orthodontics—its nature and objectives. (A. F. Jackson) 275-291  
 Australia has Empire's largest dental faculty. (M. Evan-Jones) 292-293

## 68 : January 1948

The upper respiratory musculature and orthodontics. (C. F. Ballard & E. Gwynne-Evans) 1-21

## 68 : February 1948

The physiology and mechanics of swallowing and their clinical significance. (A. A. Nove) 28-33  
A model former. (W. Grossmann) 34-35  
Australia's dentists on wheels. (N. Bartlett) 36-38

## Guy's Hospital Reports

96 : 1947

Bleeding peptic ulcer. (C. Baker) 1-56  
Liposarcoma of the breast. (S. de Navasquez & R. E. Horton) 57-59  
The temperature of choice for hot drinks: a comparison of men and women. (J. N. Hunt) 60-63  
Allergy in ophthalmology. (O. G. Morgan) 64-72  
Some experiences in the surgery of labyrinthitis. (P. Reading) 73-84  
Intestinal ulceration due to arterial necrosis (malignant hypertension and polyarteritis nodosa). (S. de Navasquez & E. B. French) 85-92  
Congenital defect of abdominal wall with spontaneous rupture in utero. (A. Hill) 93-96  
Studies in lung abscess. (R. C. Brock) 97-139

## Journal of Anatomy

81 : July 1947

Observations on the elastic tissue of the skin with a note on the reticular layer at the junction of the dermis and epidermis. (J. C. Dick) 201-211  
Experimental foetal death in the rat: histological changes in the membranes. (J. T. Pritchard & A. St G. Huggett) 212-224  
Endings produced by somatic nerve fibres growing into the adrenal gland. (D. H. L. Evans) 225-232  
Headform and human evolution. (A. A. Abbie) 233-253  
Observations on muscle-fibre structure: the swelling of muscle fibres by acids and alkalis. (R. Bajer) 259-285  
Variations in the distribution of lipoids in the adrenal cortex of the albino rat. (R. G. Harrison & A. J. Caio) 286-299  
Observations on the anatomy of the fossil Australopithecinae. (W. E. Le G. Clark) 300-333

81 : October 1947

The formation of birefringent crystals in the suprarenal cortex. (J. M. Yoffey & J. S. Baxter) 335-342  
The blood vessels of the rabbit's pituitary gland, and the significance of the pars and zona tuberalis. (G. W. Harris) 343-351  
The distribution of alkaline phosphatase in the pregnant uterus of the rat. (J. J. Pritchard) 352-364  
The regenerative capacity of cardiac muscle. (R. G. Harrison) 365-366

## Journal of Clinical Pathology

1 : November 1947

The laboratory diagnosis of virus infections of man: a review. (S. P. Bedson) 2-9  
Meningococcal meningitis with particular reference to epidemiology and pathogenesis. (R. W. Fairbrother) 10-18  
Reticulocytes and their humoral regulation. (E. Jacobsen) 19-24  
The distribution of leucocytes on the counting chamber. (M. Hynes) 25-29  
The colorimetric determination of glucose. (E. J. King & R. J. Garner) 30-33  
Familial intestinal polyposis. (C. E. Dukes) 34-38  
Report on two species of the genus *Fusiformis* obtained from pathological lesions in man. (H. Schwabacher & D. A. Mitchison) 39-43  
Diethylene glycol poisoning: report on two cases. (E. Wordley) 44-46

1 : February 1948

Iroo metabolism. (M. Hynes) 57-67  
The error of colour matching with Haldane's haemoglobinometer. (J. L. D'Silva & E. C. Turton) 68-72  
Rapid and economical Rhesus testing: a trial of Chown's capillary tube method. (G. Discombe & H. Meyer) 73-76  
A simplified Price-Jones technique. (J. G. Humble & G. Belyavin) 77-79  
The inhibition of acid phosphatases by formaldehyde and its clinical application for the determination of serum acid phosphatases. (M. A. M. Abul-Fadi & E. J. King) 80-90  
A quantitative precipitation test for syphilis. (J. N. O. Price) 91-98  
Chloral hydrate plates for the inhibition of swarming of *Proteus*. (E. H. Gillespie) 99-100

## Journal of Endocrinology

5 : November 1947

The hormonal properties of perhydrodiethylstilboestrol. (G. Brownlee & A. F. Green) 183-185  
Assay of thyroidal activity by a closed vessel technique. (A. U. Smith, C. W. Emmens & A. S. Parkes) 186-206  
A comparison of the growth of the ovum and follicle in normal rhesus monkeys, and in monkeys treated with oestrogens and androgens. (S. H. Green & S. Zuckerman) 207-219  
Duration of reproductive life in the baboon. (S. Zuckerman) 220-221

5 : January 1948

The physiological activity of the optically active isomers of thyroxine. (R. P. Rivers & J. Lerman) 223-228  
Alloxan-diabetes and liver glycogen. E. Tuerkischer & E. Wertheimer) 229-235

Adrenalectomy and replacement therapy in lactating rats. 4. Effect of deoxycorticosterone acetate on the water content of mammary tissue after adrenalectomy. (S. J. Folley & A. L. Greenbaum) 236-242  
A rapid method for volumetric and numerical estimation of pancreatic islets in the mouse. (L. E. Mount) 243-246  
The quantitative determination of small amounts of pregnandiol in human urine. (I. F. Sommerville, N. Gough & G. F. Marrian) 247-257

## Journal of General Microbiology

1 : September 1947

Observations on two very large bacteria, *Caryophanon latum* Peshkoff and *Lincola longa* (nomen provisorium). (E. G. Pringsheim & C. F. Robinow) 267-278  
The production of acetylcholine by a strain of *Lactobacillus plantarum*. (M. Stephenson & E. Rowatt) 279-296  
Addendum. The isolation of acetylcholine as a salt (hexylate) of hexanitrodiphenylamine. (K. Harrison) 296-298  
The assimilation of amino-acids by bacteria. 4. The action of triphenylmethane dyes on glutamic acid assimilation. (E. F. Gale & P. D. Mitchell) 299-313  
The assimilation of amino-acids by bacteria. 5. The action of penicillin in preventing the assimilation of glutamic acid by *Staphylococcus aureus*. (E. F. Gale & E. S. Taylor) 314-326  
The assimilation of amino-acids by bacteria. 6. The effect of protein synthesis on glutamic acid accumulation and the action thereon of sulphathiazole. (E. F. Gale) 327-334  
A method for the large-scale production of streptomycin by surface culture. (G. C. Ainsworth, A. M. Brown, P. S. S. F. Marsden, P. A. Smith & J. F. Spilbury) 335-343  
A method for extracting and purifying streptomycin suitable for large-scale production. (T. J. Woodthorpe & D. M. Ireland) 344-352  
A dilution method for the assay of streptomycin. (A. M. Brown & P. A. Young) 353-360  
Studies on soil acrasiae. 2. The active life of species of *Dicryostelium* in soil and the influence thereof of soil moisture and bacterial food. (B. N. Singh) 361-367  
Spray inoculation of plates in the detection of antagonistic micro-organisms. (A. Wilska) 368-369  
The production of stable potent preparations of penicillinase. (E. S. Duthie) 370-377  
The production of certain species of *Clostridium* of enzymes disintegrating hide powder. (D. G. Evans) 378-384  
The leucithinase of *Clostridium bifermentans* and its relation to the  $\alpha$ -toxin of *Clostridium welchii*. (E. M. Miles & A. A. Miles) 385-399

## Journal of Hygiene

45 : August 1947

An inquiry into the incidence of cross-infections, complications and return cases in scarlet fever. (D. G. H. Edward, N. Crowley, E. Topley & B. Moore) 251-264  
The epidemiology and control of *Salmonella thompson* infection of fowls. (A. Buxton & R. F. Gordon) 265-281  
Studies on the effect of penicillin upon gram-negative bacteria. Penicillin-sulphonamide synergy. (G. T. Stewart) 282-289  
Nasal filtration of airborne droplets. (E. Boyland, J. H. Gaddom & F. F. McDonald) 290-296  
The value of antiseptics as prophylactic applications to recent wounds. (J. Gordon, J. W. McLeod, A. Mayr-Harting, J. W. Orr & K. Zinnermann) 297-306  
Phage-resistant and phage-carrying strains of lactic streptococci. (G. J. E. Hunter) 307-312  
The synergic action of penicillin and sulphathiazole on *S. typhi*. (J. C. Thomas & W. Hayes) 313-326  
Feeding and breeding of laboratory animals. V. Use of Cope-Chat record cards for the analysis of breeding performance. (H. M. Bruce & A. S. Parkes) 327-332  
Studies in the dynamics of disinfection. X. The effect of lethal temperatures on standard cultures of *Bact. coli*. III. On the variation of the rate of disinfection with temperature at pH 7.0, including the calculation of a new and constant temperature coefficient. (R. C. Jordan, S. E. Jacobs & H. E. F. Davies) 333-341  
Studies in the dynamics of disinfection. XI. The effect of lethal temperatures on standard cultures of *Bact. coli*. IV. An investigation of that portion of the population which survives prolonged exposure at pH 7.0. (R. C. Jordan, S. E. Jacobs & H. E. F. Davies) 342-353  
Bog disinfection in a prison. (J. J. Landers) 354-358  
The effect of phagocytosis on the growth and survival of avian tubercle bacilli in embryonic chicken tissue cultivated *in vitro*. (H. B. Fell & E. M. Brieger) 359-370  
Sylvatic plague studies. The vector efficiency of nine species of fleas compared with *Xenopsylla cheopis*. (A. L. Burroughs) 371-396

45 : December 1947

The adjustment of biological assay results for variation in concomitant observations. (D. J. Finney) 397-406  
Isolation and maintenance of an L1-like culture from *Fusiformis necrophorus* (Syn. *Bact. funduliformis*, *Bacteroides funduliformis*). (E. Klieneberger-Nobel) 407-409  
Morphological appearances of various stages in *B. proteus* and *coll.* (E. Klieneberger-Nobel) 410-412  
Demonstration of chromatinic structures in avian tubercle bacilli in the early stages of development. (E. M. Brieger & C. F. Robinow) 413-416  
A new bacterial variant: the non-motile H form. (W. Hirsch) 417-419  
The feeding and breeding of laboratory animals. VI. The breeding of mice. (H. M. Bruce) 420-430  
Note on the effects of home duties on factory employment of women. A study of absenteeism in a group of 144 voluntary factory workers. (D. C. Wilson) 431-433  
Factors affecting warmth comfort and stuffiness in domestic rooms. (K. W. Yarnold) 434-442  
An account of the health of nurses at Westminster Hospital from July 1943 to July 1946. (E. D. H. Cowen) 443-454

Variation, diurnal and over longer periods of time, in blood haemoglobin, haematocrit, plasma protein, erythrocyte sedimentation rate, and blood chloride. (E. T. Renbourn) 455-467  
 A suggested repellent for schistosome cercariae. (W. R. G. Atkins) 468  
 Epidemic respiratory infection in a rural population with special reference to the influenza A epidemics of 1933, 1936-7 and 1943-4. (W. N. Pickles, F. M. Burnet & N. McArthur) 469-473  
 The occurrence of foot-and-mouth disease in the hedgehog under natural conditions. (J. D. McLauchlan & W. M. Henderson) 474-479  
 The conglutination phenomenon. I. An introduction to the conglutination phenomenon and an account of the observations and views of previous investigators. (N. H. Hole & R. R. A. Coombs) 480-489  
 The conglutination phenomenon. II. The technique of the conglutinating complement absorption test compared with the haemolytic complement fixation test. (N. H. Hole & R. R. A. Coombs) 490-496  
 The conglutination phenomenon. III. The test in experimental glanders. (N. H. I. . . . .  
 The bacteriological examination of mollusca (Sherwood) 504-521

### Journal of Laryngology and Otology

61 : November 1946

Labyrinthine fenestration—the present position. (C. A. Hutchinson) 567-585  
 Acute otitis externa in India. (J. V. Clark) 586-593  
 Congenital abnormalities of the pillars of the fauces and the action of the posterior pillars and nasopharyngeal valve during speech. (M. C. Oldfield & I. P. J. MacNaughtan) 594-600  
 "Considerations regarding the secondary after sensations caused by a stimulation of the semicircular canal system." Some remarks on the paper of L. B. W. Jongkees and J. J. Groen. (E. Wodak) 601-603  
 Haemorrhage from the internal carotid artery following pharyngeal abscesses. (E. C. Richardson) 604-607

61 : December 1946

Further observations on temporary deafness following exposure to gunfire. (G. Reid) 609-633  
 Mastoid asymmetry and inner-ear deafness: an unusual case. (N. A. Punt) 634-635  
 A note on chronic catarrhal tinnitus, and a method of treatment. (K. B. Bellwood) 636-640

"This issue completes the Journal for 1946 . . . it has been decided to eliminate entirely the year 1947, so that the next issue will be dated January, 1948."  
 —Editorial note attached to December 1946 issue.]

62 : January 1948

Some observations on the fundamentals of allergy: with special reference to its aural manifestations. (D. Harley) 1-10  
 Treatment of otogenic blood stream sepsis. (J. A. Harpman) 11-21  
 Some observations on bone conduction following the fenestration operation. (R. R. Woods) 22-32  
 A case of osteomyelitis of the frontal bone, treated by penicillin. (W. McKenzie) 33-35  
 Some anatomical points in the fenestration operation. (M. Hartly) 36-38

62 : February 1948

he turning test with small regulable stimuli. I. Method of examination: cupulometry. (A. A. J. van Egmond, J. J. Groen & L. B. W. Jongkees) 63-69  
 The turning test with small regulable stimuli. II. The normal cupulogram. (J. Hulk & L. B. W. Jongkees) 70-75  
 "Permanent" deafness due to gunfire. (G. Reid) 76-87  
 Osteomyelitis of the skull complicating frontal sinusitis. (R. Lewis) 88-92  
 A case of chordoma of the right frontal sinus. (W. S. Adams) 93-95  
 Percaine as a cocaine substitute. (A. S. Brown & J. Howrie) 96-99

62 : March 1948

Operative treatment of ozaena. (A. Réthi) 139-146  
 Peripheral positional nystagmus. (P. G. Gerlings) 147-162  
 Cancer of the larynx and its treatment by radium. (A. A. Charteris) 163-169  
 Progressive facial nerve palsy due to temporal epidermoid. (M. R. Sheridan & T. M. Banham) 170-172  
 A case of "tooth in tonsil." (L. Citron) 173-174

### Journal of Mental Science

93 : October 1947

Excitatory abreaction: with special reference to its mechanism and the use of ether. (H. J. Shorvon & W. Sargent) 709-732  
 The existence of critical levels for the actions of hormones and enzymes, with some therapeutic applications. (W. R. Ashby) 733-739  
 The 700th anniversary of Bethlem. (D. Whittaker) 740-747  
 Cerebral symptoms in thrombo-angiitis obliterans. (D. Perk) 748-755  
 Mepacrine psychosis. (D. Perk) 756-771  
 Schizophrenia in a boy of 11 years. (G. Garmany) 772-777  
 Treatment of epilepsies with epanutin. (R. G. R. Burrows) 778-784

### Journal of Neurology, Neurosurgery and Psychiatry

10 : August 1947

Angiomatose encéphalo-trigémine (Sturge-Weber) sans calcifications radiologiques décelables: (observation anatomo-clinique). (C. Haemerlinck, G. Myle & L. van Bogaert) 93-97: plates, 97-98  
 Diverticulum of the lateral ventricle extending into the posterior cranial fossa: report of a case successfully relieved by operation. (W. V. Macfarlane & M. A. Falconer) 101-106: plate, 100  
 A case of musicogenic epilepsy. (D. Shaw & D. Hill) 107-117

Electrical aids in prognosis of nerve injuries. (H. W. Newman & W. K. Livingston) 118-121: plate, 99  
 Electromyograms in muscular disorders. (E. Kugelberg) 122-123: plate, 129-133  
 Cerebral responses to electrical stimulation of peripheral nerve in man. (G. D. Dawson) 137-140: plates, 134-136

10 : November 1947

Investigations on a patient subject to myoclonic seizures after sensory stimulation. (G. D. Dawson) 141-162  
 Actinomycosis of the brain. (W. Lewin & A. D. Morgan) 163-170  
 Arsenical encephalopathy in Indian troops. (L. Krainer, D. A. K. Black, R. J. McGill & N. V. Rao) 171-182  
 Aphasia studied in patients with missile wounds. (F. Schiller) 183-197

11 : February 1948

Cerebellar abscess. Treatment by excision with the aid of antibiotics. (J. Pennybaeker) 1-12  
 Observations on the cause and mechanism of symptom-production in sciatica and low-back pain. (M. A. Falconer, M. McGeorge & A. C. Begg) 13-25  
 The neuropathological aspects of thrombotic acroangio-thrombosis. A clinical-anatomical study of generalized platelet thrombosis. (R. D. Adams, J. Cammermeyer & P. J. Fitzgerald) 27-43  
 Primary cerebral hydatid cysts. (G. Phillips) 44-52  
 The clinical characteristics, treatment, and rehabilitation of repatriated prisoners of war with neurosis. (M. Jones & J. M. Tanner) 53-60  
 The psychological symptoms and the physiological response to exercise of repatriated prisoners of war with neurosis. (J. M. Tanner & M. Jones) 61-71

### Journal of Obstetrics and Gynaecology of the British Empire

54 : August 1947

Sedation with rectal tri-brom-ethanol (avertin, bromethol) in the management of eclampsia. (J. B. Dewar & W. I. C. Morris) 417-425  
 The excretion of drugs in human milk—a review. (N. Sapeika) 426-431  
 Calcium and phosphorus metabolism in pregnancy. (A survey under war and post-war conditions.) First communication on the temperamental and emotional factor. (E. Obermer) 432-442  
 Studies in prematurity, stillbirth and neonatal death. Part II. Delivery and its hazards. (C. M. Drilling) 443-451  
 Studies in prematurity, stillbirth and neonatal death. Part III. Stillbirths and neonatal deaths. (C. M. Drilling) 452-468  
 A further contribution to the study of the influence of failure of Müllerian duct fusion on pregnancy and labour. (S. Way) 469-476  
 Angular pregnancy at term complicated by constriction ring. (J. T. Lows) 477-481  
 The effect of methyl-ergometrine on the human puerperal uterus. (R. C. Gill) 482-488  
 The antenatal and postnatal care of the erythroblastotic infant. (C. C. Bowley) 489-495  
 Pregnancy after the menopause. (A case-report and a review of the literature). (L. Snaith & M. Williamson) 496-498  
 The aetiology of congenital torticollis and certain associated deformities, with a suggestion for prophylaxis. (G. P. Charlewood) 499-503  
 The treatment of intractable cases of essential pruritus vulvae. (A. Horn) 504-506  
 Diencephalic monster. (S. Nowell & R. Owen-Jones) 507-509  
 Haemorrhagic disease of the unborn. (J. Morgan) 510-511

54 : October 1947

Foetal and neonatal mortality. (J. P. Greenhill) 577-591  
 Leucorrhoea in pregnancy. (A further study with special reference to the hydrogen ion concentration and lactic acid content of the vagina). (W. G. Linton, F. B. Chisholm, A. P. T. Easson, R. G. Jacomb & W. O. Kermack) 592-606  
 Causes and treatment of tubal occlusion. (L. Snaith) 607-618  
 The histaminolytic index of blood during pregnancy and its clinical application. (G. V. Anrep, G. S. Barsoum & A. Ibrahim) 619-631  
 The Manchester operation for genital prolapse. (W. F. Shaw) 632-635  
 Unsuspected tuberculous endometritis. (J. R. O'Brien & M. K. Lawlor) 636-641  
 Icterus in pregnancy. (A clinico-pathological study including liver-biopsy). (W. C. W. Nixon, E. S. Egell, W. Laqueur & O. Yahya) 642-652  
 Gestational changes in the vaginal epithelium and their relation to the sex of the foetus. (H. E. Nieburgs) 653-656  
 Bilateral ovarian dermoids in a girl of twelve. (E. M. Metcalfe) 657-658  
 Note of a case of cerebral haemorrhage occurring early in pregnancy. (S. Leter) 659-662  
 Pelvic contraction due to idiopathic steatorrhoea. (S. F. Hans) 663-664  
 Treatment of a type of juxta-urethral vesicovaginal fistula. (G. B. Thomas) 665-666  
 Smellie's method of forceps traction. (P. Malpas) 667-669  
 Achalasia of the external os (or conglutination of the external os). (J. A. Waterman) 670-672

54 : December 1947

The fourth of November, 1847: James Young Simpson and chloroform anaesthesia. (J. Miller) 729-732  
 Diagnostic and therapeutic aspects of kymographie uterotubal insufflation with comparative observations on hysterosalpingography. (I. C. Rubin) 733-745  
 Studies in the biology of the cervix and its relation to puerperal infections. (M. B. McIlraith & A. L. Idellestrand) 746-777  
 The range of blood-pressure among women who had a normal pregnancy and confinement. (W. J. Martin) 778-782  
 The value of the Guterman test in threatened abortion. (S. Bender) 783-792  
 An investigation of the causes of sterility and lowered fertility in West African negroes. (C. . . . .) 793-816  
 Calcium and . . . . . in pregnancy: (a survey under war and post-war . . . . . and phosphorus balances and antenatal findings. (E. Querner) 817-825  
 Vestibular anus: (report of a case). (J. L. Wright) 824-825  
 Cramps in pregnancy. (M. Robinson) 826-829  
 Some aspects of foetal pathology: (with special reference to the role of amniotic bands). (G. G. Lennon) 830-837

- Inevitable, incomplete and septic abortion. (G. FitzGibbon) 838-841  
 The incubation period of ophthalmia neonatorum. (A. Sorsby) 842-847  
 Further observations on the basal temperature in sterile women. (I. Halbrecht) 848-852  
 A case of spontaneous extra- and intra-peritoneal rupture of a hydronephrosis in pregnancy. (I. C. Campbell) 853-854  
 The use of a Hodge pessary for correcting backward displacement of the uterus. (T. N. A. Jeffcoate) 855-857  
 Pyrexia as a sign of endometriosis. (T. N. A. Jeffcoate) 858-860  
 Plastic surgical treatment of congenital transverse diaphragms of the vagina. (M. Tritofides) 861-862

## 55 : February 1948

- The composition of the blood of women during pregnancy and after delivery. (H. Hoch & J. R. Marrack) 1-16  
 The action of intravenously injected sex hormones and other substances on the blood flow in the human endometrium. (A. A. Loeser) 17-22  
 Amenorrhoea traumatica (atretica). (J. G. Asberman) 23-30  
 Gross hypertrophy of the pregnant uterine cervix simulating cancer. (A. Hill) 31-35  
 An accessory growth on the posterior commissure of the labia majora. (G. R. de Beer & I. G. Smith) 36-40  
 Report of a case of uterus didelphys complicating labour. (G. J. Streen & J. C. Portnuff) 41-43  
 A benign tumour of the placenta. (D. V. Davies) 44-46  
 An unusual case of infection of a sixteen weeks' extra-uterine pregnancy. (J. L. Boldero) 47-49  
 Acute rheumatism in pregnancy. (F. McKeown) 50-52  
 Testosterone propionate in inoperable carcinoma. (J. Wyatt) 53-54  
 Intracranial haemorrhage in the newborn. (C. Saunders) 55-61  
 Acute inversion of the uterus treated by Huntington's operation. (M. A. M. Bigby, P. Greaves & R. A. Kinch) 62-64  
 The effect of pregnancy on the translucence of the mammary gland. (L. Halberstaedter) 65-67  
 Elderly primigravidae. (P. C. Dutta) 68-70  
 A case of double tubal pregnancy. (P. C. Dutta) 71  
 The difficult dilatation. (E. F. Murray) 72

## Journal of Pathology and Bacteriology

## 59 : July 1947

- Accidental electrocution: with direct shock to the brain itself. (W. E. C. Dickson) 359-365  
 On the effect of the interaction of staphylococcal  $\beta$  toxin and group-B streptococcal substance on red blood corpuscles and its use as a test for the identification of *Streptococcus agalactiae*. (E. Munch-Petersen & R. Christie) 367-371  
 Coagulase-positive staphylococci resistant to penicillin. (M. Barber) 373-384  
 Inclusion bodies (protozoan-like cells) in the organs of infants. (D. F. Cappell & M. N. McFarlane) 385-398  
 The phloxin-tartrazine method as a general histological stain and for the demonstration of inclusion bodies. (A. C. Lendrum) 399-404  
 Tropical primary phlebitis. (A. C. Fisher, M. M. Fisher & A. C. Lendrum) 405-415  
 Further observations on the chemotherapy of experimental staphylococcal infection in mice with drugs of the sulphonamide group, penicillin and antitoxin. (P. Browning & K. M. Calver) 417-423  
 The effects of  $\beta$ , $\beta$ -dichlorodithyl methylamine hydrochloride on the blood-forming tissues. (G. R. Cameron, F. C. Courtice & R. P. Jones) 425-435  
 The myoepithelium in certain tumours of the breast. (R. Biggs) 437-444  
 Development of resistance of *Shigella shigae* to glycine. (J. Gordon & M. Gordon) 445-451  
 The essential lesion of pneumokoniosis in Welsh coal workers. (A. G. Heppleston) 453-460  
 A new medium for the isolation and identification of *C. diphtheriae* based on the production of hydrogen sulphide. (G. F. W. Tinsdale) 461-466  
 The role of leukotoxins in the production of the anhydremia of burn shock. (H. Cullumbe, F. McDonald & M. M. Simpson) 467-475  
 The influence of cutaneous burning and leukotoxins on the adenosine equivalent of the blood of rabbits. (H. Cullumbe) 477-479  
 An improved technique for inoculation of fertile eggs. (L. Hoyle) 480-481  
 An unsuccessful attempt to induce gliomata in rabbits with cholanthrene. (H. Russell) 481-483  
 Extensive carcinomatous change in a case of chronic ulcerative colitis. (W. M. Rose) 483-485  
 A new way of applying immersion oil. (A. Piiper) 486  
 The production of viridans variants of haemolytic streptococci. (A. Isaacs) 487-489  
 Unsuccessful attempts to produce periarthritis nodosa experimentally. (J. M. Alston, K. K. Cheng & R. H. D. Short) 490-492  
 Bilateral rhabdomyoma of the kidney. (T. J. Constance) 492-495  
 A liquid medium buffered at pH 9.6 for the differentiation of *Streptococcus faecalis* from *Streptococcus lactis*. (P. M. F. Shattock & A. Hirsch) 495-497  
 Reticulocytosis in splenectomized rabbits. (P. K. Hammick & G. M. Watson) 498-501  
 The allergic reaction of the kidney to sulphonamide medication. (K. Bakken) 501-504  
 A new *Salmonella* species, *Salm. singapore*. (VI. VII; k  $\leftrightarrow$  e, n, x). (N. K. Sen) 505-506

## 59 : October 1947

- Normal red-cell survival in men and women. (S. T. Callender, E. O. Powell & L. J. Wits) 519-532  
 A new *Salmonella* (*Salm. fayed*) which caused fatal endocarditis in man. (E. S. Anderson, H. J. Anderson & J. Taylor) 533-537  
 Liver atrophy produced by chronic selenium intoxication. (G. R. Cameron) 539-545  
 Experimental serum carditis and its relationship to rheumatic fever. (E. F. McKeown) 547-555  
 The relationship between rheumatic carditis and subacute bacterial endocarditis. (Y. MacLaine) 557-565  
 The nature and significance of the cementing substance in interstitial connective tissue. (T. D. Day) 567-573  
 Age changes in lymph nodes. (F. A. Denz) 575-591

- The effect of foster nursing on the morphology of the mammary glands in mice. (V. R. Khanolkar & K. J. Ranadive) 593-603  
 The adrenal cortex in essential and renal hypertension. (J. A. Fisher & T. F. Hewer) 605-613  
 Hepatic alkaline phosphatase: histological and microchemical studies on liver tissue in normal subjects and in liver and in bone disease. (S. Sherlock & V. Walshe) 615-630  
 Observations on the prevention of bacterial growth by sulphonamides, with special reference to the Harper and Cawston effect. (N. Walker, R. P. Philip, M. W. Smyth & J. W. McLeod) 631-645  
 A case of foetus pseudo-amorphus. (J. Svejda) 647-655  
 Bacterial "calculi." (H. B. Hewitt) 657-664  
 Growth and repair in adipose tissue. (G. R. Cameron & R. D. Senzeviratne) 665-676  
 Tuberculosis of the brain and ovary in a bird. (R. E. Rewell) 677-679  
 Natural and acquired immunity in frogs and fish. (K. A. Bisset) 679-682  
 Surgical transplantation of a carcinoma of the urinary bladder. (G. Lumb) 682-683  
 The basophilic property of the iron-containing granules in siderocytes. (J. V. Dacie & I. Doniach) 684-686  
 Ectopic decidua in the renal pelvis. (H. F. Bettinger) 686-687  
 The mechanism of swarming of *Proteus*. (I. Lominski & A. C. Lendrum) 688-691  
 Solitary adenomyoma of the uterus. (M. Haines) 691-694

## Journal of Physiology

## 106 : October 1947

- The histaminolytic action of blood during pregnancy. (G. V. Anrep, G. S. Barsoum & A. Ibrahim) 379-393  
 Cortical lipids of the normal and denervated suprarenal gland under conditions of stress. (M. Vogt) 394-404  
 The effect of calcium ions on the respiration of kidney slices of newborn and mature rats. (M. Cutting & R. A. McCance) 405-410  
 The effect of electrolytic deficiency on the rate of conduction in a single nerve fibre. (B. Katz) 411-417  
 Quantitative studies of adrenaline and noradrenaline. (G. B. West) 418-425  
 The estimation of adrenaline in normal rabbit's blood. (G. B. West) 426-430  
 Inulin, diiodine, creatinine and urea clearances in newborn infants. (R. F. A. Dean & R. A. McCance) 431-439  
 The mechanism of the sting of the common nettle (*Urtica Urens*). (N. Emmelin & W. Feldberg) 440-455  
 Some factors affecting the acidity of urine in man. (M. G. Eggleston) 456-465  
 Vagal nerve fibre activity following multiple pulmonary embolism. (E. G. Walsh) 466-470  
 The motility and viability of rabbit spermatozoa at different hydrogen-ion concentrations. (C. W. Emmens) 471-481  
 The smooth muscle contracting effects of various substances supposed to act on nervous structures in the intestinal wall. (N. Emmelin & W. Feldberg) 482-502

## 107 : January 1948

- The threshold of angular acceleration perception. (J. J. Groen & L. B. W. Jongkees) 1-7  
 Renal excretion of sodium and potassium in rats. (S. E. Dicker) 8-13  
 An automatic method for the collection of the alveolar air. (C. G. Lambie & M. J. Morrissey) 14-23  
 A note on the shape of pipettes used in blood gas analysis. (M. J. Morrissey & A. J. Palmer) 24-26  
 The nature of the acclimatization occurring during repeated exposure of the human subject to atmospheres containing low concentrations of carbon monoxide. (E. M. Killick) 27-44  
 The action of tetanus toxin on the rabbit's iris. (N. Ambache, R. S. Morgan & G. P. Wright) 45-53  
 Rods, cones and the localization of pre-excitatory inhibition in the mammalian retina. (R. Granit & K. Tansey) 54-66  
 Inspiratory vaso-constriction in patients after spinal injuries. (R. W. Gilliatt, L. Guttman & D. Whitteridge) 67-75  
 Vaso-constriction in the finger after deep inspiration. (R. W. Gilliatt) 76-88  
 The effects of pancreozymin and of vagal nerve stimulation upon the histological appearance of the pancreas. (A. A. Harper & I. F. S. Mackay) 89-96  
 Sensitivity of the small intestine. (C. B. B. Downman, B. A. McSwiney & C. C. N. Vass) 97-106  
 The action of phosgene on the stretch receptors of the lung. (D. Whitteridge) 107-114  
 The action of adrenaline on mammalian skeletal muscle. (G. L. Brown, E. Bülbring & B. D. Burns) 115-128

## 107 : March 1948

- The effect of variations in osmotic pressure and electrolyte concentration on the motility of rabbit spermatozoa at different hydrogen-ion concentrations. (C. W. Emmens) 129-140  
 The distribution of reducing substances between the intra-ocular fluids and blood plasma, and the kinetics of penetration of various sugars into these fluids. (H. Davson & W. S. Duke-Elder) 141-152  
 The action of carbon dioxide and cyanide on foetal respiratory movements; the development of chemoreflex function in sheep. (J. Barcroft & M. J. Karvonen) 153-161  
 An outflow recorder useful for detecting small amounts of vasopressin. (R. P. Stephenson) 162-164  
 The local electric changes associated with repetitive action in a non-medullated axon. (A. L. Hodgkin) 165-181  
 Phosphate clearances in infants and adults. (R. F. A. Dean & R. A. McCance) 182-186  
 The directional and spectral sensitivities of the retinal rods to adapting fields of different wave-lengths. (F. Flammant & W. S. Stiles) 187-202  
 Sulphanilamide inhibition of carbonic anhydrase in whole blood. (D. J. Anderson & L. C. Thomson) 203-209  
 The stimulating action of phosphate compounds on the perfused superior cervical ganglion of the cat. (W. Feldberg & C. Hebb) 210-221  
 The secretion of adrenaline from the perfused suprarenal gland. (E. Bülbring, J. H. Burn & F. J. De Elia) 222-232  
 Effect of ulnar nerve block on blood flow in the reflexly vasodilated digit. (W. M. Arnott & J. M. Macfie) 233-235  
 Ascorbic acid in adrenal blood. (M. Vogt) 239-243

## Journal of the Royal Army Medical Corps

89 : July 1947

- Meningococcal infections in the Army, 1939-1945. With 30 selected illustrative cases. (R. Priest) 1-28  
 An analysis of 100 consecutive operations on the knee and a report on a xanthoma of the knee-joint. (C. M. Marsden) 29-37  
 Some aspects of pneumonia among African troops in the Gold Coast and the response of this disease to sulphamerazine. (R. N. Johnston) 38-43  
 Purulent pericarditis—combined surgical and penicillin treatment. (C. W. Templeton) 44-47

89 : August 1947

- The toxic effects of two daily injections of mapharside combined with penicillin in the treatment of early syphilis. (R. R. Willcox) 49-56  
 An investigation into the possible effects of intramuscular injections of bismuth on the penicillin content of the blood serum when given concurrently with penicillin in the treatment of early syphilis. (J. W. Eames & G. T. L. Archer) 57-65  
 Saline test for streptococcal haemolysis. (S. Sevi) 66-70  
 Traumatic diaphragmatic hernia. (C. M. Marsden) 71-78  
 Penicillin in the treatment of human anthrax. (G. N. Mann) 79-81  
 The Kupat Holim. (K. Fletcher-Barrett) 81-83  
 Martial law in Tel Aviv. (K. Fletcher-Barrett) 83-90

89 : September 1947

- Acrylic ocular prosthesis. (F. J. Sellers) 91-100  
 The chemoprophylaxis of malaria. (R. W. Scott) 101-111  
 Suppression of malaria by mepacrine. (G. Wynne-Griffith) 112-121  
 Psychiatric and allied aspects of the problem of venereal disease in the Army. With particular reference to S.E.A.C. (T. A. Ratcliffe) 122-131  
 The pitressin hydration test in the diagnosis of epilepsy. (D. Cappon) 132-135  
 Sulphonamide anuria. (J. A. V. Nicoll) 135-138  
 A note on sicklog and flylog. (G. M. Fiodlay, E. A. Boulter & C. B. MacGibbon) 138-141

89 : October 1947

- its management. (J. M. Potter) 143-148  
 the main causes of death, "F" Force, 149-165  
 An appreciation of smallpox as it affects the hygiene services of the British army to-day. (R. J. Niven) 166-185  
 The bacteriophage typing of European and North African strains of *Bact. typhosum*. (J. F. Wilson) 186-187  
 Military nursing through the ages. (A. Thompson) 194-202

89 : November 1947

- Malarial episodes. A clinical study of atypical, pernicious and lethal cases selected from among 10,000 malarial patients admitted to military hospitals in Ceylon. (E. Soysa) 205-222  
 Unusual aspects and therapy in amoebic dysentery. (L. R. S. Macfarlane) 223-234  
 The parachute field ambulance. (A. D. Young) 235-249

89 : December 1947

- Unusual aspects and therapy in amoebic dysentery. (L. R. S. Macfarlane) 255-273  
 Positive health—its attainment in the soldier and the Army's contribution to it in the civilian. (A. E. Richmond) 274-289  
 Infective hepatitis. (J. Mackay-Dick) 290-300  
 Tahes dorsalis, aortic aneurism, and cutaneous syphilis presenting in the same patient. (J. W. Eames) 301-303  
 Lichen planus linearis. (R. J. McGill) 303-306

90 : January 1948

- Field ambulance sections in a mountain operation. (R. Johnston & J. F. Mawc) 1-5  
 The occurrence and identification of the typhus group of fevers in South East Asia Command. (M. H. P. Sayers & I. G. W. Hill) 6-22  
 Burma retreat 1942. (T. O. Thompson) 23-29  
 Disposal of the sick and wounded of the English Army during the sixteenth century. (D. Stewart) 30-38

90 : February 1948

- Burma retreat, 1942—Part II. (T. O. Thompson) 47-60  
 The white cell count in early syphilis of males. (R. R. Willcox) 61-64  
 The treatment of acute uncomplicated gonorrhoea in the male by means of a single intramuscular injection of oily penicillin B.P. (J. W. Eames & A. O. McClay) 65-71  
 Resuscitation of limb and abdominal wound cases in the field. (A. D. Milne) 72-84

90 : March 1948

- The early days of army psychiatry. (R. Rosie) 93-100  
 The pathology of the liver in deaths from thermal burns. (A. P. Prior) 101-108  
 Diphtheria in the Army in the United Kingdom. A study of its complications. (R. G. Paley & S. C. Truelove) 109-116

90 : April 1948

- Health education in the Army. (H. J. A. Richards) 133-148  
 Curare as an adjuvant to anaesthesia in military practice. (W. H. Scriven & K. F. Stephens) 149-154  
 March haemoglobinuria—a review. (M. Lubran & J. Sakula) 155-160  
 Morbid conditions of the knee-joint in East African askaris with particular reference to aetiology and pathology. (H. B. Youg) 161-169  
 A case of pneumococcal septicaemia. (J. Mackay-Dick) 170-171  
 A case of septicaemia (due to *Streptococcus aureus*) confused with clinical hepatic amoebiasis. (J. Mackay-Dick) 171-172

90 : May 1948

- Effects of heat with special reference to its occurrence in British troops in the Persian Gulf area in 1941-42. (W. Stewart) 178-193  
 Traumatic arteriovenous fistula: treatment and results. (J. M. Matheson) 194-213

## Journal of the Royal Institute of Public Health and Hygiene

10 : October 1947

- Home and social environmental factors and the health of the school child (J. L. Burn) 325-336

10 : November 1947

- The health of the mind. (N. Harris) 363-366

10 : December 1947

- Infantile paralysis. (H. J. Seddon) 390-395  
 The health factor in town planning. (A. Ling) 396-404

11 : January 1948

- The history of state medicine in England. *The FitzPatrick Lectures*, 1947, Lecture No. 3. (A. S. MacNalty) 9-26  
 Diet in pregnancy. (W. C. W. Nixon) 27-33

11 : February 1948

- The history of state medicine in England. *The FitzPatrick Lectures*, 1947, Lecture No. 4. (A. S. MacNalty) 48-67

11 : March 1948

- The organization of the nervous system. *The Harben Lectures*, 1947, (E. D. Adrian). Lecture No. 1. "The elements of nervous activity." 82-92. Lecture No. 2. "The effects of the sense organs." 92-101. Lecture No. 3. "The activity of the brain." 102-110

11 : April 1948

- Modern methods in the care of the aged. (L. Z. Cosin) 122-135

11 : May 1948

- The planning of a modern hospital in relation to the public health. (S. E. I. Cusdin) 153-163  
 Hygiene in the nursery school. (M. D. Sheridan) 164-171

11 : June 1948

- The opportunities of the school medical officer. (R. E. Smith) 188-193  
 The home nursing of children. (D. A. Lane) 199-203

11 : July 1948

- Disorders of childhood. (D. W. Winnicott) 244-245

## Journal of the Royal Naval Medical Service

33 : April 1947

- The Royal Naval Medical School. (R. W. Mussen) 61-67  
 The use and limitations of the portable service-afloat X-ray unit. (G. L. Hardman) 67-79  
 Acute meatal illness at sea—a study of 50 cases. (H. Osmond) 80-92  
 Anaesthesia: 100 years of progress. (H. P. Price) 92-98  
 Mass X-ray examination of the chest. (S. H. R. Price) 99-102

33 : July 1947

- Nutritional neuropathy as seen in ex-prisoners of war from the Far East. With special reference to the factors responsible for the distribution of the lesions in the central nervous system. (M. A. Rugg-Gunn) 137-177  
 Blood transfusion in the treatment of shock in the Royal Navy. (F. P. Ellis) 177-192  
 Medical aspects of a wartime Antarctic expedition: 1944-1946. (Operation Taharin). (E. H. Back) 193-197  
 D.D.T. in S.E.A.C. (D. H. Birt) 197-200  
 The measurement of the thermal environment afloat. (J. M. Rees) 200-204  
 Clinical aspects of wound shock. (J. A. Shepherd) 204-217

## Journal of Tropical Medicine and Hygiene

50 : September 1947

- The cyst-passer. (L. E. Napier) 169-174  
 Amoebic abscess of the spleen. (P. Manson-Bahr) 174-175  
 Amoebiasis, diagnostic and therapeutic considerations. (W. J. Alkan) 175-183  
 Altered tuberculin sensitivity in chronic malaria. (J. G. Makari) 183-185

50 : October 1947

- Plague in the Americas. (M. T. Hockenga) 190-201  
 Quinine injections in malaria. (C. W. F. Winckel) 201-203

50 : November 1947

- Clinical features, diagnosis, and treatment of spruce. (H. H. A. Elder) 212-218  
 The malaria patient and quinine. (C. W. F. Winckel) 219-220

50 : December 1947

- The Manson tradition. (P. Manson-Bahr) 238-243  
 Tropical ulcer, as seen in South Iran, and its treatment with penicillin. (J. M. Pinkerton) 243-251

51 : January 1948

- Quinine and congenital injuries of ear and eye of the foetus. (C. W. F. Winckel) 2-7  
 Serial cephalin flocculation curves: their application to the study of tropical diseases and their relation to a new resistance factor. (J. G. Makari) 8-20

## 51 : February 1948

- The response of intestinal amoebiasis to diodoquin treatment. (P. Manson-Bahr & W. J. Muggleton) 23-27  
 Induced malaria for treatment of general paralysis. (J. Bylmer & C. W. F. Winckel) 27-33  
 Land ownership and anti-malaria law in Malaya. (J. H. Hudson) 33-40

## 51 : March 1948

- Studies in tropical ulcer. Part I. The origin of an epidemic. (K. Hare) 47-53  
 Further observations on the macroscopic diagnosis of urinary schistosomiasis. (C. V. Meeser, W. F. Ross, & D. M. Blair) 54-59  
 Isolation of the cholera vibrio. (M. A. Gohar) 59-60

## 51 : April 1948

- Treatment of epidemic typhus with chloromycetin. (E. H. Payne, J. A. Knandt & S. Palacios) 68-71  
 Studies in tropical ulcer. Part II. The aetiology of tropical ulcer. (K. Hare) 72-81

## 51 : May 1948

- The diagnosis of rectal schistosomiasis. (C. V. Meeser, W. F. Ross & D. M. Blair) 91-94  
 Cholera in Egypt. Laboratory diagnosis and protective inoculation. (M. A. Gohar & M. Makkawi) 95-99  
 Studies in tropical ulcer. Part III. The insect vector. (K. Hare) 99-103

## 51 : June 1948

- The prognosis in schistosomiasis. (M. Gelfand) 112-119  
 Studies in tropical ulcer. Part IV. The treatment of tropical ulcer. (K. Hare) 119-128  
 The normal lobular neutrophil picture in the East African. (K. E. Dewhurst) 128-130

## 51 : July 1948

- An investigation into the causes of severe anaemia in Fiji. (G. T. Barnes) 133-139  
 Millet beer and peanuts as protective foods in Africans. (N. L. Corkill, H. Creditor & G. E. S. Stewart) 140-144  
 Cholera vaccines. (M. A. Gohar) 144-147

## Lancet

## 2 : 4/10/47

- British Anti-Lewisite: its use and therapeutic value in arsenical intoxications. A report from the BAL Conference, Medical Research Council. 497-498  
 Kidney function in diabetes insipidus. (A. Greiner & L. Podhradsky) 498-501  
 Amidone (miadone) as an obstetric analgesic: trial in 62 cases. (F. Prescott & S. G. Ransom) 501-503  
 Potassium chlorate poisoning: report of a case. (S. Gordon & J. A. H. Brown) 503-504  
 Penicillin in 1% beeswax-arachis oil. (H. Brindle, R. W. Fairbrother & F. B. Jackson) 505-506  
 Alopecia areata treated with thorium-X. (P. J. Feeny) 506-508  
 Opsoclonia: a rare ocular sign in poliomyelitis. (D. E. Marmion & J. Sandilands) 508-509  
 Revolt from the bedpan and the enema. (G. Bobmannson & H. Malmros) 509-510

## 2 : 11/10/47

- Social class and foetal mortality. (D. Baird) 531-535  
 Hypoglycaemia following partial gastrectomy: report of three cases. (C. G. Barnes) 536-539  
 Tuberculous rheumatism. (R. J. T. Woodland) 540  
 Effect of  $\beta$ -chloroethylamine hydrochlorides in leukaemia, Hodgkin's disease, and polycythaemia vera: report on eighteen cases. (J. F. Wilkinson & F. Fletcher) 540-545  
 The Rhesus antigen C<sup>w</sup> causing haemolytic disease of the newborn. (S. D. Lawler & J. J. van Loghem) 545-546  
 The metric system in medicine. (H. Finemore) 553  
 Childhood advisory clinics in Camberwell. (A. Comfort) 555-558

## 2 : 18/10/47

- Cystic disease of the breast: human and experimental. (B. D. Pullinger) 567-572  
 Syosis barbae: serological types of staphylococcus pyogenes in nose and skin and results of penicillin treatment. (B. C. Hobbs, H. L. Carruthers & J. Gough) 572-574  
 Intensive treatment of kala-azar with sodium antimonyl tartrate. (A. R. D. Adams & D. R. Seaton) 575-576  
 Gaucher's disease without splenomegaly. (M. E. Morgans) 576-578  
 The dropside cot in hospital. (W. Napier) 578-579  
 Diagnosis of adrenal tumours: a new chemical test. (J. Patterson) 580-581  
 Army health and medical administration. (H. S. Gear) 589-591

## 2 : 25/10/47

- Medicine, science, and learning. (H. Platt) 603-606  
 Acute suppurative tenosynovitis treated with systemic penicillin. (C. N. Cruickshank & S. H. Harrison) 606-608  
 Penicillin in pulp-space infections of the finger. (H. Bolton, B. N. Catchpole & R. P. Jepson) 608-610  
 Use of penicillin in acute infections of the hand. (A. L. Webster) 610-612  
 Amoebiasis in Ceylon. (T. Parkinson) 612-615  
 Congenital funnel chest. (H. S. K. Sainsbury) 615-616  
 "Fellagratic" action of maize: further experiments. (E. Kodicek, K. J. Carpenter & L. J. Harris) 616-617  
 Educational treatment of deafness. (A. W. G. Ewing & I. R. Ewing) 623-630

## 2 : 1/11/47

- The paroxysmal tachycardias. (M. Campbell) 641-647  
 The delayed immunity response. (M. Barr & A. T. Glennay) 647-649  
 Salt metabolism in acute porphyria. (G. C. Linder) 649-652  
 Spontaneous rupture of spleen after defaecation. (A. W. N. Druitt) 652-653  
 Pseudomonas pyocyanea meningitis following spinal analgesia. (I. M. Davidson) 653-654  
 Applied photography. Relation of the photographic department to the teaching hospital. (P. Hansell & R. G. W. Ollerenshaw) 663-666

## 2 : 8/11/47

- Physique and growth of schoolboys. (G. E. Friend & E. R. Bransby) 677-681  
 The paroxysmal tachycardias. (M. Campbell) 681-684  
 Pityriasis basophilism. (G. A. Penington, R. Kaye-Scott & R. J. Wright-Smith) 684-686  
 Neuropathy after stilbamidine: treatment of kala-azar. (P. J. Collard & W. H. Hargreaves) 686-688  
 Quartan malaria transmitted by blood-transfusion. (K. B. Rogers) 688-689  
 The cholera epidemic in Egypt: mode of spread. (S. Abdou) 689-697  
 Anti-cholera measures in Egypt. From a correspondent in Egypt. 697-698

## 2 : 15/11/47

- The health of authors. (H. Nicolson) 709-714  
 Prefrontal leucotomy and the depersonalisation syndrome. (H. J. Shorvon) 714-718  
 Effect of stilboestrol on mouse tumours. (R. J. Ludford & L. Dmochowski) 718-720  
 Auscultation in acute abdominal disease. (C. G. Rob) 720-721  
 Rupture of rectus abdominis muscle during pregnancy. (J. Morgan) 721-722  
 Fatal haemorrhage in aberrant lung tissue. (F. D. Hart & A. C. Jones) 722-723  
 Employment of tuberculosis staff in a sanatorium. (J. Watt & M. Sheshan) 731-732

## 2 : 22/11/47

- Pathology of sudden death. (K. Simpson) 745-746  
 The intracellular mode of action of the sulphonamide derivatives. (R. A. O. O'Meara, P. A. McNally & H. G. Nelson) 747-752  
 Staphylococcal pneumonia in childhood: pathological considerations. (K. J. Guthrie & G. L. Montgomery) 752-755  
 The chronic paretic. (B. H. Kirman) 755-757  
 Transplantation of teres major and latissimus dorsi for loss of external rotation at shoulder. (R. B. Zachary) 757-758  
 Immunisation of the mammalian embryo. (F. W. R. Brambell, W. A. Hemmings & W. T. Rowlands) 759

## 2 : 29/11/47

- A hepatic syndrome of wide distribution: illustrated by lesions in malaria and blackwater fever. (B. Macgregor, W. H. H. Andrews & D. Gall) 781-784  
 Epidemic myalgia or Bornholm disease in South India: a review of 19 cases. (H. J. Hamburger & C. McNeill) 784-786  
 Symptoms due to Meckel's diverticulum. (S. Taylor) 786-789  
 Determination of haemoglobin. II. The Haldane haemoglobin standard compared with iron and gasometric estimations. (E. J. King, M. Gilchrist, I. D. P. Wootton, R. Donaldson, R. B. Sisson, R. G. Maffiari, H. M. Jope, J. R. P. O'Brien, J. M. Peterson & D. H. Strangways) 789-792  
 Dissemination of haemolytic streptococci in air. (L. Colebrook & W. P. D. Ross) 792-794  
 Calciferol in the treatment of chilblains. (S. T. Anning) 794  
 Geriatric rehabilitation. (L. Z. Cosin) 804

## 2 : 6/12/47

- Teachers of medicine. (F. M. R. Walshe) 817-820  
 Personality change after prefrontal leucotomy. (L. Frankl & W. Mayer-Gross) 820-824  
 Therapeutic abortion by means of soft-soap pastes. (H. H. F. Barnes) 825-827  
 The viability of *Treponema pallidum*. (C. E. Lumsden) 827-829  
 Intrabronchial penicillin for lung abscess. (E. Rosenthal) 829-830  
 An easy technique for intravenous cannulation. (A. Clain) 830  
 Glandular enlargement in adults. (H. M. R. Jones) 830-831  
 Streakiness of blood films. Relation to sedimentation-rate and plasma-fibrinogen. (R. M. Boveri, R. L. Waterfield & T. H. Newman) 831-832  
 The problem of gastric cancer. (A. Shorter) 842-845

## 2 : 13/12/47

- Absorption of penicillin given by mouth. (H. C. Stewart & J. R. May) 857-862  
 Speech after repair of cleft palate. (F. H. Bentley & I. Watkins) 862-865  
 Triene analgesia: simple apparatus for self-administration. (J. T. Hayward-Butt) 865-867  
 Holt's diphtheria toxoid (P.T.A.P.) Al PO<sub>4</sub> content, purity, ageing, and durability of immunity. (G. Bousfield) 867-870  
 Antisera in the treatment of allergic diseases. (C. J. C. Britton) 870-871  
 Para-aminosalicylic acid in tuberculosis: early results of clinical trials. (T. G. Dempsey & M. H. Logs) 871-872  
 The urgent need for reforms in hospitals. (L. A. Parry) 881-883  
 Avoidable meningitis. Memorandum from the Public Health Laboratory Service and the London Sector Pathologists' Committee. 883-884  
 Hospital catering. A comparison with arrangements in American hospitals. (M. C. Broatch) 884-885  
 New York's health insurance plan. (R. Davison) 886

## 2 : 20/12/47

- Treatment of tuberculosis with streptomycin and sulphathione. (D. G. Madigan, P. N. Swift, G. Brownlee & G. P. Wright) 897-904  
 Primary splenic abscess. (M. Gelfand) 904-905  
 Antithyroid activity of ergothioneine in man. (E. B. Astwood & M. M. Stanley) 905-906  
 Comments. (A. Lawson & C. Rimmington) 905-907  
 Wernicke's encephalopathy simulating diabetic coma. (F. A. Jones & V. C. Robinson) 907-909  
 Death from renal anoxia after myaesthesia anaesthesia. (T. F. Hewer & R. F. Woolmer) 909-910  
 Bilateral zoster. (E. W. P. Thomas) 910-911  
 The effect of miracid D on human schistosomiasis. (D. M. Blair, F. Hawking & W. F. Ross) 911-912  
 Diet and disease in the Subarctic. (A. C. Duncan) 919-921

## 2 : 27/12/47

- Visceral pain. (H. Cohen) 933-935  
 A comprehensive student-health service. (A. H. Macklin) 935-937  
 Compulsory physical education for university students. (R. H. Bolton) 938-939  
 Health examinations of students. Pilot survey in Oxford. (R. W. Parnall) 939-941

- Familial idiopathic methaemoglobinemia. Five cases in one family. (Q. H. Gihson & D. C. Harrison) 941-943  
Rh factor and haemolytic disease of the newborn in Jerusalem Jews. (J. Gurevitch, A. Brzezinski & Z. Polshuk) 943-944  
Membranous nature of interstitial connective tissue. (T. D. Day) 945  
Glossopharyngeal zoster followed by varicella in two contacts. (F. J. Wright) 946-947  
Detection of latent genital tuberculosis by culture of menstrual discharge. (L. Halbrecht) 947-948  
Mass radiography in the early diagnosis of chest disease. (E. G. W. Hoffstaedt) 955-958

## 1 : 3/1/48

- Shock in obstetrics. (H. L. Sheehan) 1-7  
The initiation of cellular infection by influenza and related viruses. (F. M. Burnet) 7-11  
Ankylosing spondylitis. (W. Lennon & I. S. Chalmers) 12-15  
Action of tetraethyl ammonium bromide. (A. M. Boyd, G. R. Crawshaw, A. H. Ratcliffe & R. P. Jepson) 15-18  
Tetraethyl ammonium bromide in hypertension and hypertensive heart-failure. (G. W. Hayward) 18-20  
Folic acid in nutritional anaemia. (J. W. D. Goodall, H. I. Goodall & D. Banerjee) 20-21  
Streptomycin in human plague. (P. V. Karamchandi & K. S. Rao) 22  
Canine hysteria and wheat. (H. Parry) 32-34  
Modern Hospitals. I. A French architect's view. (J. Walter) 36-38

## 1 : 10/1/48

- The psychological aspects of sanatorium management. (G. S. Todd & E. Wittkower) 49-53  
Excision of the elbow-joint. (W. H. Kirkaldy-Willis & C. V. Braimbridge) 53-57  
Significance of palatal movements in diphtheria. (R. M. Maher) 57-60  
Clinical extracorporeal dialysis of blood with artificial kidney. (N. Alwall, L. Norviit & A. M. Steins) 60-62  
Sensitisation of penicillin-resistant bacteria. (A. Vourekka) 62-65  
Thrombocytopenic purpura with thyrotoxicosis. (G. F. Roberts) 65-66  
Recurrent bullous eruption of feet. Report of a case. (S. P. Hall-Smith & F. O'N. Daunt) 66-67  
Modern Hospitals. II. Children's Clinic, Helsinki. (A. Ylppö) 75-76

## 1 : 17/1/48

- The pneumonias associated with epidemic respiratory infections. (J. G. Scadding) 89-93  
Treatment of arthritis by intra-articular injection. (D. M. Baker & M. S. Chayen) 93-97  
Virulence of gravis strains of *Corynebacterium diphtheriae*. (J. W. McLeod & D. T. Robinson) 97-100  
Phalangeal metastases in bronchogenic carcinoma. (G. M. Colson & A. Willeox) 100-102  
Vitamin E in angina pectoris. (D. H. Makinson, S. Oleesky & R. V. Stone) 102  
Recurrent agranulocytosis. (G. M. G. Barton) 103  
Modern Hospitals. III. Karliska Hospital, Sweden. (S. Lindgren) 113-115

## 1 : 24/1/48

- Media of health education. (C. Bibby) 125-127  
Chemotherapy and pharmacology of aerosporin. A selective gram-negative antibiotic. (G. Brownlee & S. R. M. Bushby) 127-132  
Treatment of pertussis with aerosporin. (P. N. Swift) 133-135  
Fractures of the mandible with oedema of the neck and tongue: the early treatment. (N. W. A. Holland) 135-138  
Perforation of the colon in dysentery. Two cases of recovery after operation. (J. A. W. Bingham) 139-140  
Recto-urethral fistula. (R. K. Magee) 140  
Trichiniasis presenting with foot-drop and facial palsy. (M. Macandrew & E. Davis) 141  
Modern Hospitals. IV. Hospitals in the United States. (C. T. Maitland) 152-154

## 1 : 31/1/48

- What is gout? (F. W. Jones) 165-167  
Plantar warts. A plea for rational treatment. (C. R. McLaughlin) 168-169  
Liver disease in Johannesburg: relation to pellagra. (J. Gillman & T. Gillman) 169-173  
Artificial pneumothorax. Survey of 150 inductions on outpatients. (A. Maclean & J. S. Gemmill) 173-175  
Seasonal incidence of retarded growth in children with nutritive failure. (S. Dreizen, A. W. Mann & T. D. Spies) 175-177  
Failure of sulphonamides and penicillin in maduromycosis. (A. Dostrovsky & F. Sagher) 177-178  
Modern Hospitals. IV. Hospitals in the United States. (Concluded.) (C. T. Maitland) 186-188

## 1 : 7/2/48

- The country doctor. (W. N. Pickles) 201-203  
Bronchial carcinoma presenting as polyneuritis. (R. Wyburn-Mason) 203-206  
Treatment of schistosomiasis. (B. Girgis & S. Aziz) 206-209  
Clicking pneumothorax. (W. Fox) 210-212  
Phosphatase and bone formation. (A. Siessor & G. M. Wyburn) 212-213  
Acute subdural haematoma: amenable to surgical treatment. (N. Whalley) 213-214  
Fatal hypoglycaemia in a diabetic. (J. L. Winkler) 215-216

## 1 : 14/2/48

- The principles of B.C.G. vaccination. (A. J. Wallgren) 237-239  
Treatment of nutritional macrocytic anaemia with synthetic folic acid. (T. D. Spies, G. G. Lopez, F. Milanes, R. E. Stone, R. L. Toca & T. Aramburu) 239-241  
Classification of peripheral-nerve injuries. (R. Roaf) 242-243  
Treatment of amoebic dysentery. (A. W. Wright & A. E. R. Coombes) 243-246  
Primary meningococcal conjunctivitis in children. (R. D. Stuart & D. McWalter) 246-248  
Supra-renal haemorrhage and pregnancy. (C. W. F. Burnett) 249-250  
Modern Hospitals. V. Roskilde Hospital, Denmark. (K. Bierring) 264-266

## 1 : 21/2/48

- Problems in the treatment of myelitis. (D. M. Horstmann) 271-272  
Diphtheritic . . . . . last. (A. D. Leigh) 277-280  
Tuberculous . . . . . of remaining . . . . . (P. C. Pym & J. D. T. Jones) 280-282  
Determination of haemoglobin. III. Reliability of clinical and other methods. (R. G. Macfarlane, E. J. King, I. D. P. Wootton & M. Gilchrist) 282-285  
Crush syndrome and traumatic uraemia. (J. H. Hicks) 286-287  
Chronic bilateral spontaneous pneumothorax. Difficulties in treatment. (C. F. Hawkins) 288-289

## 1 : 28/2/48

- Tuberculous cervical adenitis. (H. Bailey) 313-316  
The essential pathology of kwashiorkor. (J. N. P. Davies) 317-320  
Nose and skin carriage of *Staphylococcus aureus* in patients receiving penicillin. (B. Moss, J. R. Squire, E. Topley & C. M. Johnston) 320-325  
Properties of bovine serum heated with formaldehyde. (C. E. Boesen, V. Lenz & A. K. Nielsen) 325-327  
Retropharyngeal lipoma. (J. C. McFarland) 327  
Calcium content of skin in lupus vulgaris treated with calciferol. (K. M. Tomlinson) 327-328  
Modern Hospitals. VI. Hospitals in Switzerland. (C. T. Maitland) 338-341

## 1 : 6/3/48

- The connexions of the frontal lobes of the brain. (W. E. Le G. Clark) 351-355  
Functions of the frontal lobes. (W. R. Russell) 356-360  
The imbalance of vitamins: with particular reference to folic acid. (L. S. P. Davidson & R. H. Girdwood) 360-363  
Melioidosis treated with sulphonamides and penicillin. (E. J. Harris, A. A. G. Lewis, J. W. B. Waring & E. J. Dowling) 363-366  
Myanesis in hyperkinetic states. (A. R. Hunter & J. M. Waterfall) 366-368  
Myanesis as an aid to anaesthesia in children. (H. B. Wilson & H. E. Gordon) 367-368  
The nicotinic-acid tolerance test. (A. Erdei) 368-369  
Immunisation against some virus diseases of animals. (J. Francis) 377-378  
Streptomycin trials: preliminary report. 378-379  
Modern Hospitals. VII. Planning a general hospital. Some Canadian suggestions. 380-381

## 1 : 13/3/48

- Brachial neuralgia. (W. R. Brain) 393-395  
Formation of hepatic glycogen in normal Africans and in those suffering from malignant malnutrition. (E. G. Holmes & H. C. Trowell) 395-398  
Spinal-cord lesions in cerebrospinal fever: report of four cases. (J. W. A. Turner) 398-402  
Necrobacillosis: report of two cases. (G. D. Owen & M. S. Spink) 402-403  
Recovery of streptomycin from urine. (J. Müller & D. Rowley) 404  
Carcinoid causing obstruction. (G. J. Fraenkel) 404-406  
Massive tonsillar lymphatic adenitis. (J. D. Gray & J. Garson) 406-408  
Clicking pneumothorax related to walking. (A. B. Black) 408  
Nitrogen-mustard therapy combined with splenectomy. (E. Rosenthal) 408  
Aged sick nursed at home. (T. Ferguson) 417-419

## 1 : 20/3/48

- The full-time specialist. (F. A. Jones) 433-436  
Assessment of intestinal carcinatives. (S. Alstead & J. F. Patterson) 437-439  
Actinomycosis of the liver with recovery. (L. M. Shorvon) 439-441  
Results of sympathectomy of the upper limb: with special reference to Raynaud's disease. (H. Barcroft & G. T. C. Hamilton) 441-444  
Electronarcosis: its value and its dangers. (G. Garmany & D. F. Early) 444-446  
Fructose and fructolysis in semen in relation to fertility. (T. Mana) 446-448  
Incidence of epilepsy in children of school age. (P. Henderson) 455-457

## 1 : 27/3/48

- Treatment of rheumatoid arthritis. (W. S. Tegner) 469-472  
Vesicocapsular prostatectomy. (R. O. Ward) 472-474  
Anti-histamine drugs in asthma. (R. B. Hunter & D. M. Danlon) 474-476  
Gonococcal meningitis treated with penicillin and sulphamezathine. (B. P. Moore, M. J. G. Lynch, P. C. Reynell & W. H. Donald) 476-477  
Determination of haemoglobin. IV. A comparison of methods for determining iron content and oxygen capacity of blood. (E. J. King, M. Gilchrist, I. D. P. Wootton, J. R. P. O'Brien, H. M. Jope, P. E. Quelch, J. M. Peterson, D. H. Strangeways & W. N. M. Ramsay) 478-483

## Medical Officer

## 78 : 4/10/47

- Emergency maternity homes, 1939-45. (M. L. Marsh) 145-149  
The sex-ratio at birth. (I. A. G. MacQueen) 149-150  
Ministry of Health return of infectious diseases. 152

## 78 : 11/10/47

- Smoke and the public health. (A. Macgregor) 157-159  
Factors influencing the future provision of day nurseries. (Day Nurseries Committee, National Women's Federation) 159-161  
. . . . .uation Scheme. (H. Keast) 161-162  
. . . . . of infectious diseases. 164

## 78 : 18/10/47

- The old at home: an account of an enquiry undertaken at Ramsgate. (J. V. Walker) 169-174  
Ministry of Health return of infectious diseases. 176

## 78 : 25/10/47

- The control of acute poliomyelitis: an epidemic in Bad Pyrmont, Germany, 1945. (L. Hahn & I. Taylor) 181-183  
Ministry of Health return of infectious diseases. 186

78 : 1/11/47

Effect of immunisation on diphtheria carrier rate. (V. F. Soothill) 191-192  
The functions and organisation of an almoner's department. (A statement issued by the Council of The Institute of Almoners.) 192-194  
National Health Service (Superannuation) Regulations, 1947. 194-195  
Ministry of Health return of infectious diseases. 198

78 : 8/11/47

Plantar warts in school children with special reference to treatment by curettage. (K. McAlpine) 203-205  
The reinstatement of the family. (A. D. Symons) 205  
Ministry of Health return of infectious diseases. 208

78 : 15/11/47

The social implications of medico-psychological disorders. (C. O. Stallybrass) 213-216  
Ministry of Health return of infectious diseases. 218

78 : 22/11/47

Mental hygiene in the Netherlands. (A. Querido) 223-224  
Limitations of hygiene and sanitation. (C. Thomas) 224-225  
Ministry of Health return of infectious diseases. 226

78 : 29/11/47

Measles and giant-cell pneumonia. (N. E. R. Archer & R. Biggs) 231-234  
Ministry of Health return of infectious diseases. 238

78 : 6/12/47

The family doctor and the new health service. (N. S. Dickson) 243-245  
Remote work in a V.D. centre. (E. M. J. Cooper) 245-246  
Ministry of Health return of infectious diseases. 248

78 : 13/12/47

The importance of mental hygiene in preventive medicine. (H. S. Bury) 253-257  
Ministry of Health return of infectious diseases. 259

78 : 20/12/47

Handicapped children—record cards. (H. Cotton & J. L. Burn) 265-266  
Remote control in health administration. (P. H. Turton) 266-267  
Ministry of Health return of infectious diseases. 268

78 : 27/12/47

The years of victory: a geriatric commentary. (R. J. Matthews) 273-275  
Remedials—posture classes. (N. Reed) 275-276

79 : 3/1/48

Progress and aims of public health in America. 5-7  
Ministry of Health return of infectious diseases. 8

79 : 10/1/48

Tuberculosis in Spain. (H. Sutherland) 13-14  
Social medicine in the curriculum. (A. Strom) 14-17

79 : 17/1/48

Medical health services for elderly persons. (C. Rolleston) 25-26  
Economy of bed usage in tuberculosis. (H. E. Hilleboe) 26-27  
Water supplies in South African townships. (F. G. Cawston) 27  
Ministry of Health return of infectious diseases. 30

79 : 24/1/48

The control of phlebotomus fever. (A. B. Semple) 35-37  
Ministry of Health return of infectious diseases. 40

79 : 31/1/48

Streptomycin therapy. 45-46  
National Milk Testing and Advisory Scheme. (W. W. Baum) 46-47  
Ministry of Health return of infectious diseases. 49

79 : 7/2/48

The common cold. (C. H. Andrews) 55-58  
Ministry of Health return of infectious diseases. 62

79 : 14/2/48

A health education unit. (W. L. Burgess) 67-68  
Ministry of Health return of infectious diseases. 71

79 : 21/2/48

Some modern trends in social health. (A. Davidson) 77-81  
Ministry of Health return of infectious diseases. 83

79 : 28/2/48

The assessment of the bacterial quality of ice-cream. (G. J. Laws) 89-91  
Ministry of Health return of infectious diseases. 94

79 : 6/3/48

The midwife in Northern Ireland. (A. T. Elder) 99-102  
Ministry of Health return of infectious diseases. 105

79 : 13/3/48

The control of scabies. (G. H. Percival) 111-112  
Ministry of Health return of infectious diseases. 115

79 : 20/3/48

Experiments with DDT and Gamma B.H.C. ("Gammexane") for use against head lice. (J. R. Busvine, J. L. Burn & R. Gamlin) 121-124  
Ministry of Health return of infectious diseases. 127

79 : 27/3/48

Planning for the chronically ill. 133-135  
Ministry of Health return of infectious diseases. 138

## Medical Press

218 : 1/10/47

The value of penicillin in the treatment of venereal diseases. (T. Anwyl-Davies) 293-303  
Depressed fractures of the malar bones caused by motor accidents. (M. C. Oldfield) 303-305  
The iron deficiency anaemia of late infancy. (H. W. Fullerton) 306-308  
Induction of labour. (P. L. Playfair) 308-312

218 : 8/10/47

The treatment and prognosis of chronic suppurative otitis media in children. (J. H. O'Donnell) 323-327  
Internal derangement of the knee. (H. J. Burrows) 328-331  
A survey of our sub-nutrition. (N. Leyton) 331-334  
Notes on radiology in the diagnosis of gastric and duodenal lesions. (F. T. Burkit) 334-337

218 : 15/10/47

The modern treatment of squint. (A. J. Cameron) 345-350  
The importance of diet in chronic rheumatism. (H. L. Milles) 351-355  
Hardship and neglect in childhood as a cause of adult crime. (R. R. Prewer) 355-359

218 : 22/10/47

The treatment of hypertension. (T. East) 366-369  
Diseases which man may acquire from his pets. (G. Lapage) 369-378  
The use of Di-isopropyl Fluorophosphonate, D.F.P., in paralytic ileus—a preliminary report. (J. P. Quilliam & T. A. Quilliam) 378-381

218 : 29/10/47

Congenital hypertrophic pyloric stenosis. (R. H. Dobbs) 389-393  
Avian metabolism: the bed-rock of bird-migration. (C. J. Patten) 393-399  
Radium in the treatment of ectopic pregnancy. (E. F. Blumberg) 399-401  
Angina pectoris associated with diabetes mellitus. (J. H. Hannan) 401-402

218 : 5/11/47

Ménière's disease. (T. Cawthorne) 408-411  
Indications for and against spinal analgesia and prevention and treatment of complications. (J. A. Lee) 412-416  
Benign Cushing's syndrome and its treatment. (E. Lyon) 417-421  
Rehabilitation of the aged sick. (J. H. Crosland) 421-422

218 : 12/11/47

The treatment of congenital talipes. (G. Herzfeld) 431-435  
Defective colour vision and its practical importance. (A. M. Macgillivray) 435-438  
The treatment of neurosyphilis. (J. E. Nicole) 439-442  
Heart disease and pregnancy. (J. Barnes) 443-446

218 : 19/11/47

Acute poliomyelitis. (W. H. Kelleher) 452-457  
The modern treatment of cerebrospinal fever. (L. J. M. Laurent) 457-461  
Diphtheria to-day. (J. C. McEntee) 461-464  
The management of patients in breathing machines. (J. V. Armstrong) 464-469  
Whooping cough: treatment and prophylaxis. (W. Gunn) 470-473

218 : 26/11/47

The management and treatment of haemophilia. (J. F. Wilkinson) 481-483  
The first principles of hospital planning. (R. Ward) 483-487  
Polyarteritis (periarteritis) nodosa. (A. P. M. Page) 487-490  
Urinary infection. (S. Power) 490-495

218 : 3/12/47

Acute frontal sinusitis. (G. H. Bateman) 502-504  
Diet and the soil: modern views. (L. J. Picton) 504-509  
The surgical treatment of peptic ulcers. (A. Lyall) 509-513  
Aetiology and incidence of foetal malformation. (J. Herring) 514-517

218 : 10/12/47

The Emergency Medical Services (England and Wales). Part I.—The inter-war period: historical survey. (C. L. Dunn) 525-530  
Principles of diagnosis of pulmonary tuberculosis—I. (A. L. Banyai) 530-535  
Intestinal obstruction in the new-born. (M. A. Kharadly) 536-538

218 : 17/12/47

The treatment of nasal polypi. (R. R. Simpson) 546-547  
The Emergency Medical Services (England and Wales). Part II.—The war period: the outbreak of the war. (C. L. Dunn) 548-553  
Investigation and treatment of diseases of the Fallopian tube. (A. Davis) 553-554  
Principles of diagnosis of pulmonary tuberculosis—II. (A. L. Banyai) 554-560

218 : 24/12/47

Differential diagnosis and treatment of pyogenic osteomyelitis of the vertebral column. (J. P. Gair) 569-572  
Renal angiospasm and renal cortical anoxia as the cause of acute puerperal anuria, calculus reflex suppression of urine, traumatic suppression of urine (crush syndrome), some acute toxic and septicemic anurias, and anuria in some cases of acute nephrosis and nephritis and after loss of haemoglobin. (F. P. Weber) 572-575  
The rationale and efficacy of bed rest in the treatment of pulmonary tuberculosis. (A. L. Banyai) 575-581  
Favourite prescriptions. (H. Pullar-Strecker) 581-582

## 135 : December 1947

- The research laboratories of the General Electric Company. (C. C. Paterson) 1-12  
 The Plymouth laboratory of the Marine Biological Association of the United Kingdom. (F. S. Russell) 12-25  
 The antidiuretic hormone and the factors which determine its release. Croonian Lecture. (E. B. Verney) 25-106  
 Glutinosin : a fungistatic metabolic product of the mould *Metarrhizium glutinosum* S. Pope. (P. W. Brian, P. J. Curtis & H. G. Hemming) 106-132

## 135 : June 1948

- The Kodak research laboratories. (C. E. K. Mees) 133-147  
 Croonian Lecture. The formal genetics of man. (J. B. S. Haldane) 147-170  
 A discussion on the physiology of resistance to disease in plants. Physiology of the facultative type of parasite. (W. Brown) 171-179. Host resistance to fungi, chiefly in relation to obligate parasites. (F. T. Brooks) 180-186. Some effects of host-plant physiology on resistance to viruses. (F. C. Bawden) 187-195  
 The haemoglobin of *Daphnia*. (H. M. Fox) 195-212  
 Mitotic activity in the adult male mouse, *Mus musculus* L. The diurnal cycles and their relation to waking and sleeping. (W. S. Bullough) 212-233  
 The effects of experimentally induced rest and exercise on the epidermal mitotic activity of the adult male mouse, *Mus musculus* L. (W. S. Bullough) 233-242  
 The quantitative investigation of the vertebrate brain and the applicability of allometric formulae to its study. (D. Sholl) 243-258

## Proceedings of the Royal Society of Medicine

## 40 : September 1947

- Discussion on the treatment of toxic goitre. 609-616  
 Discussion : treatment of the lymphadenopathies. 617-622  
 Discussion on the present status of infectious disease control in continental Europe. 623-632  
 Common cold. Interim report on a transmission experiment. [Abstract] (C. H. Andrews, W. H. Bradley, D. K. M. Chalmers & F. Fulton) 632-634  
 Teratomas and mixed tumours in animals and their bearings on human pathology. [Summary] (R. A. Willis) 635-636  
 Some glandular tumours of the dog. (E. Cotchin) 636-638  
 Discussion on the span of life. 638-644  
 Discussion on treatment of non-tuberculous amyotonia. 645-652  
 The packing of abdominal incisions in hernia. (I. L. L. & J. S. 652-654  
 The concentration of penicillin in bile. (J. G. Topley & J. S. 655-656  
 Discussion : the laboratory diagnosis of virus infections. 657-668  
 Carcinoma of the thyroid. (J. M. Graham & R. McWhirter) 669-680

## 40 : October 1947

- Discussion on penicillin in neurology. 681-686  
 Discussion on cerebral oedema. 686-698  
 The diagnosis and treatment of tumours of the nasopharynx. (E. D. D. Davis) 707-712  
 The pre-history of midwifery. [Abridged] (I. H. Flack) 713-722  
 Painful disability of the shoulder in coronary disease. (A. Schott) 733-736  
 Collapse of the lower lobes of the lungs in children. (N. C. Oswald) 736-737  
 Osteomalacia. [Summary] (J. P. Maxwell) 738-740  
 The complex behaviour of high-frequency currents in simple circuits. (P. Bauwens) 741-748  
 Haemophilus influenzae and its relation to epidemic influenza. (A. B. Rosher) 749-760

## 40 : November 1947

- Transmeatal attico-antrotomy in chronic tympanomastoid suppuration. (A. Tumarkin) 761-772  
 Discussion : the management of patients with essential hypertension. 773-780  
 Discussion : the present position in regard to the pneumoconioses. 781-786  
 Some experiences with bone tumours. [Abridged] (J. F. Brailsford) 787-794  
 Injuries to the bladder. (R. A. Mogg) 795-798  
 Injuries of the urethra. [Abridged] (D. S. Poole-Wilson) 798-804  
 Some observations on a personal series of battle casualties involving the genito-urinary system. [Abridged] (G. E. Parker) 804-807  
 Treatment of hydronephrosis associated with abnormal vessels. (H. H. Stewart) 807-810  
 Discussion on the treatment of syphilis with penicillin. 811-816  
 Discussion on illumination. 822-828  
 An explanation of the difference between a papilloma and an adenoma of the rectum. (C. E. Dukes) 829-830  
 Right hemicolectomy. (E. G. Muir) 831-833  
 Malaria control with D.D.T. on a national scale—Greece, 1946. [Abridged] (J. M. Vine) 841-848

## 40 : December 1947

- Certain anatomical and physiological considerations in paralysis of the larynx. (V. E. Negus) 849-853  
 The treatment of subacute maxillary sinusitis especially in children. (G. E. Archer) 854-858  
 The normal temporal horn and its deformities by tumours in the middle cerebral fossa. [Abstract] (E. Lindgren) 859-862  
 The importance of statistics in psychiatry. (L. S. Penrose) 863-870  
 Lesions of the anorectal region. 876-880  
 Toeing in plastic surgery. (D. N. Matthews) 881-883  
 Wounds of open wounds. (I. B. Sneddon) 883-884  
 Elbow-joint. (D. Wainwright) 885-886  
 Legg-Perthes' disease. The radiographic changes outside the femoral head. (H. G. Korvin) 886-891  
 Cases and case records illustrating orthopaedic and plastic surgical team work. (T. P. Kilner) 892-895  
 The Brittain method of arthrodesis of the hip. (H. H. Langston) 895-898  
 Discussion on some recent developments in knowledge of the physiology of the breast. 899-906  
 Discussion on some aspects of surgical and radiological treatment of carcinoma of the cervix. 907-922  
 Discussion on anterior poliomyelitis. 923-932

## 41 : January 1948

- Discussion on the association of otitis media with acute non-specific gastro-enteritis of infants. 1-14  
 The peep-show technique for pure tone audiometry in young children. (M. R. Dix & C. S. Hallpike) 15-16  
 Discussion on post-operative thrombosis. 17-28  
 A note on the centenary of the use of anaesthesia in obstetric practice by J. Y. Simpson. (J. C. Moir) 28-30  
 Pes planus or instability of the foot. (J. C. Moir) 31-40  
 Discussion on chemotherapy in acute anterior poliomyelitis in London. (A. Daley) 52-60  
 Some atypical primary tuberculous lesions. (M. Macpherson) 60-64  
 Considerations on the treatment of detachment of the retina. (H. Arruga) 68-72

## 41 : February 1948

- Modern trends in prostatic surgery. [Abridged] (W. W. Galbraith) 73-84  
 The influence of the small animal breeder on biological research. [Abridged] (R. E. Glover) 85-92  
 Surgical records. (M. Page) 113-118  
 Discussion : the treatment of cancer of the breast. [Abridged] 118-132

## 41 : March 1948

- Posture in anaesthesia. [Summary] (J. K. Hasler) 133-137  
 Artificial respiration. (E. A. Pask) 138-142  
 Discussion : some urological problems in gynaecological surgery. 143-150  
 Snoring. (I. G. Robin) 151-153  
 Progress in the treatment of mastoid infection and some of its complications. (D. Watson) 155-164  
 The history of cholera in Great Britain. (E. A. Underwood) 165-173  
 Epidemiology of cholera. [Summary] (J. Taylor) 174-176  
 Bacteriological and immunological aspects of cholera. [Summary] (P. B. White) 176-178  
 Discussion on the place of child guidance in the new health service. 179-182  
 Discussion : the aetiology of infantile enteritis. 182-186

## 41 : April 1948

- Discussion on Simmonds's disease. [Summary] 187-195  
 Discussion : juvenile delinquency with special reference to remand homes. 197-208  
 Discussion on the dietetic service of the hospitals of the future. 209-216  
 Discussion : plasma protein fractions. 217-224  
 The serious limitations and erroneous indications of biopsy in the diagnosis of tumours of bone. (J. F. Brailsford) 225-236  
 Discussion on the electro-encephalogram in organic cerebral disease. 237-250  
 Surgery in the treatment of rheumatoid arthritis and ankylosing spondylitis. (W. A. Law) 251-260

## 41 : May 1948

- The capsular complications of cataract extraction. (C. Goulden) 271-280  
 The inhibition of dental caries by fluorine. (R. Weaver) 284-290  
 Electromyography. (P. Bauwens) 291-298  
 Discussion on the management of uterine inertia in the first stage of labour. 311-316  
 Discussion on the treatment of septic abortion. 317-322  
 Discussion on nutrition and resistance to infection. 323-328  
 Discussion on swine erysipelas infection (*Erysipelothrix rhusiopathiae*) in man and animals. 328-332  
 A statistical analysis of geriatric care. (L. Cosin) 333-336  
 Discussion on renal circulation. 339-342

## 41 : June 1948

- Growth and physical performance of children in relation to maturity. (R. W. B. Ellis) 343-348  
 Surgical lectures of 150 years ago. (V. Z. Cope) 353-358  
 Discussion on the surgical treatment of hypertension. 359-372  
 The role of physiotherapy in the treatment of poliomyelitis. (F. S. Cooksey) 395-401  
 Infantile cerebral palsy. (P. R. Evans) 402-406  
 Some points in management of infantile cerebral palsy. (J. H. Crosland) 406-408

## Public Health

## 61 : October 1947

- Haemolytic disease of the newly-born and the Rh factor. (F. Stratton) 3-4  
 Health centres. 5-10  
 A projected health centre in Leeds. 11-12

## 61 : November 1947

- The economics of public health. (F. Hall) 21-22  
 The influence of environment on health in childhood. (N. B. Capon) 23  
 The co-ordination of the institutional care of children with the child welfare and school health services. (W. E. Crosbie) 23-25

## 61 : December 1947

- The challenge of Section 28. (E. K. Macdonald) 37-38  
 The Manchester School of Public Health. (E. H. Walker) 39-40  
 Prospects in epidemiology. (W. J. Doyle) 41-43  
 Voluntary organisations as agents of the local health authority. (C. M. Smith) 44-45

## 61 : January 1948

- The epidemiology of the 1947 outbreak of poliomyelitis in Eccles. (W. P. Sweetnam) 55-59  
 Epidemiological notes on cases of poliomyelitis and polioencephalitis occurring in the Lancashire county area. (F. W. Bunting) 59-60

The epidemiology of salmonellosis in Manchester in 1947. (A. B. Semple) 60-62  
(A. B. Christie) 62-64  
Ladywell Hospital, June to October, 1947. (W. Edge) 64-65

### 61 : February 1948

77-81  
crochery and cutlery in civilian and military  
The hygiene of drinking utensils in licensed houses. (H. J. Bunker) 85-88  
Dental care of the child under the National Health Service Act. (D. E. Mason) 89-91

### 61 : March 1948

Some thoughts on the future of public health and of the M.O.H. (R. H. Parry) 102-104  
Environmental factors affecting health and efficiency in warships. (F. P. Ellis) 104-107

### 61 : April 1948

Mental health in relation to the family: with some reference to the National Health Service Act, 1946. (C. O. Stallybrass) 123-128  
Mental subnormality in the community. (D. H. H. Thomas) 129-132  
Health at a world jamboree. (D. D. Payne) 132-134

### 61 : May 1948

The future maternity and child welfare service. (S. C. Gawne) 144-146  
Some of the medico-social aspects of venereal diseases. (W. V. Macfarlane) 147-149  
The epileptic child. (J. T. Fox) 149-150  
The treatment and management of the "spastic" child. (E. Collis) 150-151

### 61 : June 1948

Some aspects of prevention of infection through food and drink. (W. R. Martine) 165-167  
The dental care of the child under the National Health Service Act. 167-172

## Quarterly Journal of Experimental Physiology

### 34 : March 1948

Factors influencing the penetration of the skin by chemical agents. (H. Cullumbyne) 83-89  
The glycolytic activity of the hearts of vertebrates. (J. J. Wu & I. Chang) 91-95  
The influence of vitamin E on ovarian structure in mice. (Z. Menschik) 97-113  
The relationship of the thyroid gland to muscular work performed by the albino rat. (L. W. Cox) 115-122  
Determination of blood volume in dog by means of visually labelled erythrocytes. (A. Nizet) 123-128  
Haemoglobin concentration, haematocrit value, and sedimentation rate of horse blood. (G. Fegler) 129-139  
An application of bone-marrow cultures to toxicology and therapeutics. (K. Harrison & F. W. Randall) 141-149  
Note on a method for the demonstration of pulmonary vasomotor fibres. (I. de B. Daly & H. Duke) 151-158

## Quarterly Journal of Medicine

### 16 : October 1947

An outbreak of severe infective hepatitis in Burma. (J. F. Stokes & A. A. Miller) 211-236  
The effect of the injection of acetylcholine into the brachial artery of normal subjects and patients with myasthenia gravis. (A. Wilson & H. B. Stoner) 237-243  
The cryptogenic acquired haemolytic anaemias. (J. A. Fisher) 245-262  
Ascites in chronic disease of the liver. (G. Higgins, A. R. Kelsall, J. R. P. O'Brien, A. M. Stewart & L. J. Witts) 263-274  
Studies on the mechanism of the Fanconi syndrome. (J. M. Stowers & C. E. Dent) 275-290  
Snake-bite by *Echis carinata*. (R. H. Mole & A. Everard) 291-303

### 17 : January 1948

Chronic haemolytic anaemia with haemoglobinuria. The Marchiafava-Micheli syndrome. (M. D. Hickey & L. K. Malley) 1-8  
Anomalies of intestinal absorption of fat. II. The haematology of idiopathic steatorrhea. (W. T. Cooke, A. C. Frazer, A. L. P. Peeney, H. G. Sammons & M. D. Thompson) 9-24  
Idiopathic pulmonary haemosiderosis (essential brown induration of the lungs). (W. G. Wyllie, W. Sheldon, M. Bodian & A. Barlow) 25-48  
The treatment of arsenical dermatitis with dimercaptopropanol (BAL). A. B. Carleton, R. A. Peters & R. H. S. Thompson) 49-79  
Remarks regarding chronic jaundice. (F. P. Weber) 81  
Severe hypertension in young persons. A study of 50 cases. (R. Platt) 83-93

### 17 : April 1948

The Schönlein-Henoch syndrome (anaphylactoid purpura). (D. Gairdner) 95-122  
A case of chronic porphyria associated with recurrent jaundice. (C. H. Gray, C. Rimington & S. Thomson) 123-137  
Does sodium salicylate cure rheumatic fever? (J. Reid) 139-151  
The toxic manifestations of sodium salicylate therapy. (J. D. P. Graham & W. A. Parker) 153-163  
Experimental observations on chronic agranulocytosis. (G. Hickie) 165-174

## Quarterly Journal of Pharmacy and Pharmacology

### 20 : October-December 1947

Report of a symposium on new emulgents and ointment bases. (G. R. Boyes) 481-501  
A spectrophotometric method for the identification and assay of visammin and of khellinins. (K. Saman, A. M. Hossein & M. S. El Ridi) 502-504

The absorption spectra of visammin and of khellinins as indications to the chemical structure of the two compounds. (K. Saman, A. M. Hossein & M. S. El Ridi) 504-507

An investigation of the nephelometric method of estimating inorganic and ester sulphates in urine. (N. Senior) 507-518

Note on the biological assay of tubocurarine. (G. B. West) 518-527  
The evaluation of the bactericidal activity of ethylene glycol and some of its monoalkyl ethers against *Bacterium coli*. Part III. Conversion of the sigmoid survivor-time disinfection curve to a linear relationship. (H. Berry & I. Michaels) 527-537

The administration of penicillin in oil-wax suspensions. (B. H. Chantrell & M. R. Gurd) 538-540

The stability of adrenaline solutions. Part IV. Solutions of adrenaline ascorbate and other storage experiments. (G. B. West) 541-545  
Chemotherapeutic exploration of the pyridine nucleus: substituted amines. Part I. (G. G. Kalthod & W. H. Linnell) 546-551

### 21 : January-March 1948

The identification of the clinically-important barbiturates. (G. E. Turfitt) 1-9  
Tuberculostatic activity and chemical constitution. Part II. The activity of derivatives of diphenylamine-2-carboxylic acid. (A. A. Goldberg, H. S. Jefferies & H. S. Turner) 10-16

Some observations on the determination of glucuronic acid in urine. (N. Senior) 16-23

The evaluation of the bactericidal activity of ethylene glycol and some of its monoalkyl ethers against *Bacterium coli*. Part IV. (H. Berry & I. Michaels) 24-34

The alkaloids of clubmosses. (J. Muszynski) 34-38  
Pimento: a numerical study of its sclereids. Including the determination of pimento in mixtures. (T. E. Wallis & D. K. Santra) 38-44

The evaluation of tragacanth by means of the apparent viscosity determined in a standard U-tube viscometer. Part I. Powdered gum. (W. P. Chambers) 44-57

The condensation of isatin with phenols in alkaline solution: hydroxyacridine-mesocarboxylic acids. (W. H. Linnell & L. K. Sharp) 58-62  
Chemotherapeutic exploration of the pyridine nucleus: substituted amines. Part II. (G. G. Kalthod & W. H. Linnell) 63-66

## Rheumatism

### 3 : October 1947

Sciatica and the intervertebral disc. (E. A. Jack) 122-125  
A practical hypothesis for chrysotherapy. (H. Coke) 126-130  
Arthrodesis of the hip joint in degenerative arthritis. A modified one-stage procedure with internal fixation. (J. A. Dickson & L. J. Wilken) 131-138  
The treatment of rheumatoid and infective arthritis by the sulphadiazines, with special reference to "Proseptasins", sulphadiazine and sulphaguanidine. (L. J. A. Parr & E. A. Shipton) 139-153

### 3 : January 1948

The British Rheumatic Association. (F. Herniman-Johnson) 154-156  
Hip joint reconstruction by vitallium mould arthroplasty. (W. A. Law) 157-161  
The painful foot: its aetiology and treatment. (F. Baker) 162-165

### 4 : April 1948

Surgical treatment of degenerative arthritis of the hip. Aricular deservation. (L. Tavernier) 176-179  
The treatment of rheumatic polyarthritis with acid azo compounds. (N. Svartz) 180-185  
The radiological interpretation of chronic rheumatic arthritis. (D. W. Seth-Smith) 186-192  
Manipulation of the atlas and axis. (R. Keane) 193-196

## Thorax

### 2 : December 1947

Giant bullous cysts of the lung. (P. R. Allison) 169-175 : plates, 181-185  
Mediastinal cysts of bronchial origin. (P. R. Allison) 176-180 : plates, 186-190  
Treatment of broncho-pulmonary suppuration by local injection of penicillin: report of 63 cases. (H. Métras & J. Lieutier) 196-202 : plates, 191-193  
Complete occlusion of the superior vena cava with chronic mediastinitis in a case of generalized actinomycosis. (J. P. D. Mounsey) 203-205 : plate, 194  
Radiotherapy in cancer of the thoracic oesophagus. (J. A. C. Fleming) 206-215 : plate, 195  
The results of thoracoplasty in pulmonary tuberculosis. (T. H. Sellers) 216-223

### 3 : March 1948

Hydatid disease of the lung. (A. Logan & H. Nicholson) 1-14  
Dissociated paralysis of the diaphragm following phrenic crush and pneumoperitoneum. (W. Fox) 15-19  
Peptic ulcer of the oesophagus. (P. R. Allison) 20-42  
Calcified foci within the thorax of English children. (B. C. Thompson) 43-44  
Intra-pulmonary calcification and histoplasma sensitivity. (B. H. McCracken) 45-47  
Cavernous haemangioma of the lung: report of a case. (W. P. Cleland) 48-52

### 3 : June 1948

Cardiospasm. (G. H. Wooler) 53-70  
The treatment of pulmonary hydatid disease. (M. P. Susman) 71-73  
Liver biopsy in sarcoidosis. (J. G. Scadding & S. Sherlock) 79-87  
Recurrent and chronic spontaneous pneumothorax. (R. C. Brock) 88-111  
Pneumonia in North-West London, 1942-4: I. Bacterial pneumonias. (J. H. Humphrey, H. Joules & E. D. Van Der Walt) 112-121  
The influence of costal and abdominal pressure on the action of the diaphragm in normal and emphysematous subjects. (H. Herxheimer) 122-126  
Haemorrhage after extrapleural pneumonolysis. (W. P. Cleland) 127-125

## Transactions of the Royal Society of Tropical Medicine and Hygiene

41 : September 1947

- Experimental chemotherapy of filariasis. (J. T. Culbertson) 18-43. Discussion. 44-54  
 Discussion on amoebiasis. 55-91  
 Studies on the genus *Shigella*. (L. M. Gonzalez, P. Morales-Otero & J. E. Perez) 93-107  
 Sprue and coeliac disease in tropical Africa. (M. Gelfand) 109-118  
 Ovine piropilasmoses in Iraq. (S. M. Khayyat & A. A. Gilder) 119-126  
 Serological tests for syphilis in treated *Plasmodium falciparum* malaria. (M. G. Nelson) 127-132  
 Measurement of the concentration of miracil in biological fluids. (A. L. Latner, R. V. Coxon & E. J. King) 133-140  
 An epidemic of louse-borne relapsing fever in Kenya. (P. C. C. Garnham, C. W. Davies, R. B. Heisch & G. L. Timms) 141-170

41 : October 1947

- Prisoners of war camps in the Middle East and their medical problems. (S. Smith) 185-186  
 Ainhum in a leper. (E. Montestruuc & P. Caubet) 187-188  
 Mixed deficiency diseases in India : a clinical description. (R. Passmore) 189-206  
 Enzyme-purification of polyvalent antivenene against southern and equatorial African colubrine and viperine venoms. (E. Grasset & P. A. Christensen) 207-211  
 Zinc sulphate flotation of faeces. (R. Elsdon-Dew) 213-216  
 The sedimentation rate in the African peasant with special reference to trypanosomiasis. (C. Hollins & E. Lewis-Fanning) 217-240  
 Serum lipides in tropical sprue. (D. A. K. Black & J. A. Simpson) 241-254  
 Transitory neurological signs in sleeping sickness. (M. Gelfand) 255-258  
 The influence of the suspending fluid on the survival of sporozoites *in vitro*. (J. M. Tonkin) 259-262  
 The suppressive and schizonticidal value of paludrine (100 mg.) in vivax malaria. (A. W. Woodruff) 263-267  
 The aetiology of desert sore. (S. T. Anning) 268

41 : December 1947

- The practice of tropical medicine in London. (P. Manson-Bahr) 269-294  
 A rickettsial disease in East Africa transmitted by ticks (*Rhipicephalus simus* and *Haemaphysalis leachi*). (G. W. A. Dick & E. A. Lewis) 295-326  
 Typhus in Northern Nigeria. I. Epidemiological studies. (T. H. L. Montgomery & F. H. Budden) 327-337  
 Typhus in Northern Nigeria. II. Laboratory investigations. (G. M. Findlay & B. G. T. Elmes) 339-352  
 Typhus in Northern Nigeria. III. Clinical studies. (T. H. L. Montgomery & F. H. Budden) 353-362  
 A case of fièvre boutonneuse in Cyprus. (G. Partelides) 363-364  
 Observations on the action of paludrine on malarial parasites. (M. J. Mackerras & Q. N. Ereole) 365-376  
 Outbreaks of sprue during the Burma campaign. (F. Ayrey) 377-406  
 Growth of protozoa in tissue culture. IV. *Plasmodium lophurae*, exoerythrocytic forms, *in vivo* and *in vitro*. (I. M. Tonkin & F. Hawking) 407-414  
 Polymorphism in *Trypanosoma simiae* and the morphology of the metacyclic forms. (A. T. Culwick & H. Fairbairn) 415-418  
 Infection of man with *Leptospira bovis* in Palestine. (S. Btsh) 419-426

41 : January 1948

- The control of sleeping sickness in Nigeria. (J. L. McLetchie) 445-480  
 Sleeping sickness of an unusual type in Sierra Leone and its attempted control. (R. D. Harding & M. P. Hutchinson) 481-512  
 A complement fixation test for the diagnosis of relapsing fever. (B. Wolstenholme & J. H. S. Gear) 513-517  
 The effect of diet and helminthic treatment on African school children. (O. D. Macnamara) 519-524  
 Folic acid in severe nutritional anaemia : a report of five cases. (G. A. B. Cowan) 525-535  
 The chylomicron count in normal subjects and patients with sprue. (L. P. R. Fourman) 537-544  
 Growth of protozoa in tissue culture. V. *Leishmania donovani*. (F. Hawking) 545-554  
 Studies on liver damage in acute malaria. (J. Kleeberg & D. Birnbaum) 555-566  
 Splenectomy in the tropics. (A. C. Lovett-Campbell) 567-573

41 : March 1948

- Symposium on leprosy :  
 Recent advances in the treatment of leprosy. (E. Muir) 575-582  
 The eye in leprosy. (E. W. O'G. Kirwan) 583-590  
 Three cases of leprosy treated with diasone. (A. R. D. Adams) 591-594  
 Discussion. 595-599  
 The developmental cycle of *Hepatoxystes (Plasmodium) kochi* in the monkey host. (P. C. C. Garnham) 601-616

- Schistosomiasis in the Kota Kota district of Nyasaland. (O. N. Ransford) 617-628  
 Comparative merits of sternum, spleen and liver punctures in the study of human visceral leishmaniasis. (E. A. Ho, T.-H. Soong & Y. Li) 629-636  
 An account of blood count results in Sierra Leone. (M. Gosden & J. D. Reid) 637-640  
 The protein content of cerebrospinal fluid in trypanosomiasis. (K. R. Hill) 641-644  
 The surgical treatment of the large elephantoid scrotum. (A. C. Lovett-Campbell) 645-646  
 Plague controlled in Haifa by the use of D.D.T. alone. (J. S. M. Pollock) 647-656  
 Results of an investigation of the therapeutic action of paludrine and pamaquin on acute attacks of benign tertian malaria. (J. F. Monk) 657-662  
 Results of an investigation of the therapeutic action of pentaquin on acute attacks of benign tertian malaria. (J. F. Monk) 663-668  
 Quinine by continuous intravenous drip in the treatment of acute falciparum malaria. (J. H. Strahan) 669-676  
 Failure of neo-arsphenamine in relapsing vivax malaria. (J. W. Field, R. S. Johnston & H. Smith) 677-678  
 Phlebotomus in New Guinea and nearby islands. (M. S. Ferguson & O. H. Graham) 679-684

41 : May 1948

- Pathological processes in malaria. (B. Macgrath) 687-699  
 The liver lesions in malaria. (W. H. H. Andrews) 699-704  
 The exoerythrocytic parasites of *Plasmodium cynomolgi*. (H. E. Shortt & P. C. C. Garnham) 705-716  
 Bancroftian filariasis. Biological mechanisms that underlie its periodicity and other of its clinical manifestations. (C. Lane) 717-784  
 The pre-erythrocytic development of *Plasmodium cynomolgi* and *Plasmodium vivax*. (H. E. Shortt & P. C. C. Garnham) 785-795  
 Transmission of kala-azar to the Australian marsupials *Trichosurus vulpecula* and *Pseudocheirus laniginosus*. (A. Bolliger & T. C. Backhouse) 797-814  
 The occurrence of tick-borne typhus in West Africa. (G. M. Findlay & G. T. L. Archer) 815-818  
 Human microcoeliasis in Nigeria. (P. J. L. Roche) 819-820  
 A note on bilharziasis in West African troops. (A. C. Lovett-Campbell) 821-822  
 Notes on nervous and mental diseases encountered in Nigeria. (A. C. Howard) 823-828  
 Haemoglobin and plasma-protein levels in West Africa. (J. D. Stephen) 829-831

## Tropical Diseases Bulletin

44 : September 1947

- The toxicity of mepacrine in man. (G. M. Findlay) 763-779

45 : January 1948

- Sleeping sickness in Tanganyika Territory, 1922-1946. (H. Fairbairn) 1-17

45 : February 1948

- Avoidable meningitis. Memorandum drawn up by the Public Health Laboratory Service and the London Sector Pathologists' Committee. 127-129

## Ulster Medical Journal

16 : May 1947

- Ophthalmology : advances in treatment, with special reference to penicillin. (J. R. Wheeler) 1-5  
 Recent advances in oto-rhino-laryngology with special reference to penicillin therapy. (K. Hunter) 6-12  
 The results of sympathectomy. (H. A. Haxton) 13-17  
 Results of sympathectomy in the upper limb. (G. T. C. Hamilton) 18-26  
 The problem of endometriosis : a review. (W. R. Sloan) 27-32  
 Success and faddery. (F. M. B. Allen) 33-40  
 The adrenal of the newborn. (M. McNeill) 41-45  
 Giant follicular lymphoblastoma (Brill-Symmers' disease). (J. F. Pantridge) 46-53  
 Some aspects of the pathogenesis of cardiac tuberculosis. (J. M. Beare) 54-65  
 Simmonds' disease. (J. M. Beare) 66-74

16 : November 1947

- Some aspects, historical and otherwise, of surgery of the thorax. (G. R. B. Purce) 87-101  
 Some landmarks in surgical technique. (H. C. Lowry) 102-113  
 Acute intestinal obstruction. (G. D. F. McFadden) 114-131  
 Intra-thoracic actinomycosis presenting as empyema. (R. A. Pyper) 132-137  
 The heraldry of medicine. (R. W. M. Strain) 138-141

VOLUME 6  
1949–1950

BMB 1291–1620

EDITOR: A. DEWAR DUFF M.B. CH.I

THE BRITISH COUNCIL 65 DAVIES STREET LONDON W.1

# CONTENTS OF VOLUME 6

## NUMBER 1-2. *Mental Health*

### Part One: SYMPOSIUM

	PAGE		PAGE
1291 THE INTERNATIONAL CONGRESS ON MENTAL HEALTH, LONDON, 1948 ... J. R. Rees	5	1298 PROGRESS OF PSYCHOANALYSIS IN GREAT BRITAIN ... W. Clifford M. Scott	31
1292 PSYCHOLOGY AND MENTAL HEALTH. CURRENT TRENDS AND THEIR IMPLICATIONS ... F. C. Bartlett	7	1299 THEORIES OF THE ACTION OF PHYSICAL METHODS OF TREATMENT IN PSYCHIATRY ... Denis Hill	36
1293 EDUCATIONAL PSYCHOLOGY: ITS IMPLICATIONS FOR MENTAL HEALTH ... Cyril Burt	11	1300 SOMATIC ASPECTS OF MENTAL HEALTH AND DISEASE ... Derek Richter	44
1294 ASSESSMENT OF PERSONALITY ... H. J. Eysenck	16	1301 CHILD PSYCHIATRY ... Emanuel Miller	49
1295 RECENT DEVELOPMENTS IN THE MEASUREMENT OF INTELLIGENCE AND SPECIAL ABILITIES ... P. E. Vernon	21	1302 JUVENILE DELINQUENCY ... Norwood East	52
1296 THE CONTRIBUTION OF ANALYTICAL PSYCHOLOGY TO PSYCHOTHERAPY ... Michael Fordham	24	1303 MENTAL ASPECTS OF SENESCENCE ... Felix Post	54
1297 THE POSITION OF PSYCHOANALYSIS IN GREAT BRITAIN ... Edward Glover	27	1304 STUDY AND TREATMENT OF THE CRIMINAL, AND CARE OF THE MENTALLY DEFECTIVE AND MENTALLY ABNORMAL CRIMINAL ... Norwood East	57
		1305 THE LAW RELATING TO TEMPORARY TREATMENT IN MENTAL HOSPITALS ... Cyril F. Penton	59

### Part Two: COMMENTARY

1306 ASPECTS OF THE PSYCHOPATHOLOGY OF OLD AGE REVEALED IN WITCHCRAFT CASES OF THE SIXTEENTH AND SEVENTEENTH CENTURIES ... Sona Rosa Burstein	63
1307 HYPNOTISM AND SUGGESTION: THEIR PLACE IN PSYCHOTHERAPY ... William Brown	72
1308 SHOULD ANTHROPOID APES BE EXCLUDED FROM THE HUMAN FAMILY TREE? ... Arthur Keith	74
1309 HOW MUCH DO CHILDREN EAT? ... J. R. Mavrack	76
1310 EUGENICS: INTELLIGENCE AND GENIUS ... Cyril Burt	78
1311-1324 ANNOTATIONS AND NEWS ... Laurence Dopson	79
1325 EDINBURGH AND MENTAL SCIENCE	86

### HISTORY DOCUMENTATION

1326 ST. PATRICK'S HOSPITAL, DUBLIN ... H. P.	87
1327 MEDICAL AND SCIENTIFIC PHILATELY ... Douglas Guthrie	88
1328 DISSEMINATED SCLEROSIS: AN EARLY ACCOUNT ... L. T. Morton	88
1329 PROCTOLOGY IN ANCIENT EGYPT ... S. S. B. G.	89
1330 AN ENCYCLOPAEDIA OF MEDICAL SOURCES AND EPONYMS ... L. T. Morton	89
1331-1405 BOOK REVIEWS ...	90
1406 SHORTER NOTICES ...	124
1407 BOOKS RECEIVED ...	137
1408-1412 FILMS ...	143
1413 GUIDE TO THE JOURNALS ...	145

## NUMBER 3. *Mental Health Services*

### Part One: SYMPOSIUM

1414 POSTGRADUATE STUDY IN MENTAL HEALTH IN BRITAIN ... Aubrey Lewis	185	1419 THE EDUCATION OF MENTALLY DEFECTIVE CHILDREN ... Isabel M. Laird	204
1415 THE PLACE OF MENTAL HEALTH IN THE MEDICAL CURRICULUM ... D. R. MacCallman	188	1420 MENTAL HEALTH COMMUNITY CARE ... Kenneth Soddy	207
1416 OCCUPATIONAL THERAPY AND MENTAL HEALTH ... E. Mary Macdonald	191	1421 THE PRESENT POSITION OF MENTAL NURSING IN ENGLAND ... Olive F. Griffith	211
1417 MENTAL HEALTH AND THE NATIONAL HEALTH SERVICE ... W. S. MacLay	197	1422 BRITISH ORGANIZATIONS CONCERNED WITH MENTAL HEALTH: A BIBLIOGRAPHY OF BRITISH BOOKS AND PERIODICALS ... Derek Richter	213
1418 SOCIAL WORK AND SOCIAL WORKERS IN THE MENTAL HEALTH SERVICES ... Ruth Darwin	202		

Part Two: COMMENTARY HISTORY DOCUMENTATION

	PAGE		PAGE
1424-1432 ANNOTATIONS AND NEWS ...	224	1437 MEDICINE IN THE WESTERN WORLD	
1433 A NOTE ON BRITAIN'S CONTRIBUTION TO MENTAL NURSING ...	228	S. S. B. Gilder	231
1434 JAMES COWLES PRICHARD AND "MORAL INSANITY" ...	228	1438-1523 BOOK REVIEWS ...	232
1435 SIR GILBERT BLANE 1749-1834 ...	229	1524 SHORTER NOTICES ...	276
1436 VESALIUS: ANATOMIST (1514-1564) R. Paramore	230	1525 BOOKS RECEIVED ...	278
		1526-1527 FILMS ...	280
		1528 GUIDE TO THE JOURNALS ...	281

# NUMBER 4. *Neurophysiology*

Part One: SYMPOSIUM

1529 BRAIN METABOLISM AND ACTIVITY		1534 SENSORY DISCRIMINATION: WITH SOME RECENT EVIDENCE FROM THE OLFACTORY ORGAN ...	
H. McIlwain	301	E. D. Adrian	330
1530 THE RESPONSES OF MOTONEURONES		1535 LOCALIZATION OF FUNCTION IN THE CEREBRAL CORTEX ...	
J. C. Eccles	304	Geoffrey Jefferson	333
1531 THE ROLE OF ACETYLCHOLINE IN THE CENTRAL NERVOUS SYSTEM ...	312	1536 ANATOMICAL RELATIONSHIPS BETWEEN THE CEREBRAL CORTEX AND THE HYPOTHALAMUS W. E. Le Gros Clark & Margaret Meyer	341
1532 CONDUCTION OF THE NERVOUS IMPULSE: SOME RECENT EXPERIMENTS A. L. Hodgkin	322	1537 THE HYPOTHALAMUS AND ENDOCRINE GLANDS... G. W. Harris	345
1533 CEREBRAL RESPONSES TO NERVE STIMULATION IN MAN... G. D. Dawson	326	1538 THE AUTONOMIC SYSTEM OF MAN: DIGITAL VASOMOTOR RESPONSES ... E. A. Carmichael	351

Part Two: COMMENTARY HISTORY DOCUMENTATION

1539 ANTIBIOTICS ...	F. R. Selbie	356	1545 PAUL EHRLICH ...	T. S. Work	362
1540-1542 ANNOTATIONS AND NEWS ...		358	1546 WILLIAM HARVEY ...	L. T. M.	363
1543 THE ROYAL COLLEGE OF SURGEONS OF ENGLAND 1800-1950 ...	W. R. Le Fanu	360	1547-1617 BOOK REVIEWS ...		364
1544 THE DIFFERENTIATION OF FUNCTION OF THE ANTERIOR AND POSTERIOR ROOTS: HISTORICAL BACKGROUND Laurence Dopson		361	1618 SHORTER NOTICES ...		395
			1619 BOOKS RECEIVED ...		396
			1620 GUIDE TO THE JOURNALS ...		398

# INDEX TO VOLUME 6

The figures after each entry are the serial numbers of individual items, except where otherwise stated. Entries referring to annotations and news are followed by the letters (AN), entries referring to book reviews by the letters (BR), entries referring to film reviews by the letters (FR), and entries referring to historical articles and notes, bibliographical notes, and comment, by the letters (HBC). Names printed in large capitals are those of authors who have contributed articles to the symposia.

## Introduction

The range of the articles in this number of the *British Medical Bulletin* gives a good though not complete impression of the breadth of the field which is now covered by psychiatry. In the past decade, and even since the end of the war, there has been a phenomenal increase in the intensity and the extent of the work done by psychiatrists, and done by others along psychiatric lines. It looks as though psychiatry may cease to be a purely medical discipline, for its boundaries now considerably overstep the limits of what can legitimately be called *psychological medicine*. The expansiveness of this activity is in large part due to the inspiration provided by psychoanalysis. From the account which Dr. Rees gives of the Congress on Mental Health held in London in 1948, one may see how ideas, which were originally derived from the psychotherapy of the individual, have recently been applied to the psychology of groups, with implications for the management of human relations in their most general form and even of world affairs. Psychoanalysis is as much a philosophy as a branch of medicine; and its basic concepts have found their way, not only into non-medical scientific fields such as sociology and anthropology, but also into literature and art.

Even the critics of psychoanalysis will admit that a revolution in psychology was begun by the publication of Freud's early papers at the end of the last century. Before that time the normal psychology of the individual was almost unbelievably arid. It was above all Freud's discovery that the springs of human action lie deeply buried in functional levels of nervous activity of which the individual himself is unconscious, and the discovery of a method of penetrating to those levels, that have transformed both medical and lay views on the interpretation of human behaviour. Freud began his career as a neurologist, and his

of hereditary factors in the endogenous psychoses, in personality development, and even in the constitutional predisposition to neurosis.

Of all the biological sciences, it is probably psychology which has had the greatest recent impact. The extent of the field which psychology and psychological medicine hold in common may be seen in the number and variety of contributions from psychologists to this number. The influence of psychology is shown both in the formulation of concepts and in the provision of techniques of investigation. Statistics, which now play such an important part in psychiatric research, have been introduced to psychiatry from psychology. As Sir Cyril Burt says, its distinctive characteristic consists in "the scrupulous adoption of scientific techniques in place of the old-fashioned reliance on personal experience, traditional precepts, and unaided commonsense." Psychiatry has gone a long way by the use of these older methods; nor can they ever be entirely out-dated. Before one can plan an experiment, one must have some idea of the question it will be framed to answer; and the questions will generally be raised by personal experience and commonsense, though never finally answered by them. We must hope that one day the scientific approach will be universally applied in psychiatry, and when that day comes psychiatry will be able to claim the full stature of a science. Apart from these invaluable gifts of method, we owe to psychology large stretches of conquered territory. It is psychologists, more than medical men, who have clarified the subject of mental deficiency, and have shown how much can be attributed to normal

variation, and what a relatively small proportion is attributable to pathological agents. In this field the work of psychologists and geneticists has been complementary, and readily combined, as both groups necessarily applied mathematical methods. It seems likely that the contribution of psychology will be as important to the study of temperament as to that of intelligence. And wherever psychiatry impinges on the non-pathological a psychological training provides weapons which a purely medical one does not.

It must not be thought that within psychiatry all these various trends of development are combined in a spirit of absolute harmony. Different schools offer different, even mutually exclusive, interpretations of the same phenomena. Where two ideas are in contradiction, we cannot expect to preserve both, and one or other must fall. Often the contradiction will not be of a fundamental kind, and we must look forward to the time of finding the higher synthesis which will resolve apparent antitheses. Yet we may be sure that in our harvest there are the seeds of many weeds, which, however strong their growth, will have to be eliminated. By their fruits we shall know them. In the present time of stormy growth there has been little leisure for the exercise of much-needed destructive criticism. Speculation, of which there has perhaps been overmuch in psychiatry, has its place, but cannot live unless it is subjected to, and survives, rigorous testing. When the tests are made, though we may have to abandon many cherished ideas, we can be reasonably sure that the present epoch will be found to have established much solid achievement.

Eliot Slater

## Notes on Contributors

SIR FREDERIC C. BARTLETT is Professor of Experimental Psychology and Director of the Psychological Laboratory in the University of Cambridge, and a Fellow of St. John's College, Cambridge. He is a member of the Medical Research Council, Chairman of the Industrial Health Research Board and a member also of the Personnel Research Committees of the fighting Services. His own work has been concerned principally with problems of perception and remembering, and later with the development of the experimental studies of human skill behaviour. Among his more recent publications are *Remembering: an experimental and social study* (1932), and *Political propaganda* (1941); he also edited, with others, *The study of society* (1939).

SIR CYRIL BURT is Professor of Psychology in the University of London. He was educated at Oxford and Würzburg, held appointments in the School of Physiology at Liverpool under Sherrington, and in the Psychological Laboratory at Cambridge under Myers. From 1914 to 1931 he was Psychologist to the London County Council (Education Department) and during the later part of this time he also held the Chair of Educational Psychology in the University of London. He is a Fellow of the British Psychological Society and has worked on research in child guidance, vocational guidance, mental testing, psychoneurosis, and delinquency. He is at present Head of the Psychological Laboratory, University College, London, and member of

the War Office Advisory Committee on Personnel Selection and Honorary Consulting Psychologist to the Civil Service. Sir Cyril Burt's main publications are: *Distribution of educational abilities* (1917), *Mental and scholastic tests* (1921), *The young delinquent* (1925), *The measurement of mental capacities* (1927), *The subnormal mind* (1935), *The backward child* (1937) and *The factors of the mind* (1940); in addition, he is editor of the *British Journal of Psychology (Statistics)*.

SIR NORWOOD EAST is an authority on criminology and forensic psychiatry. He was educated at King's College School and King's College, London, and at Guy's Hospital. He has been for many

years lecturer in Forensic Psychiatry at the Institute of Psychiatry, Maudsley Hospital, London, and is one of the medical men appointed from time to time by the Home Secretary to report on the mental state of a prisoner on whom the capital sentence has been passed. He was formerly one of H.M. Commissioners of Prisons and Director of Convict Prisons, an inspector under the Inebriates Act, and during the Second World War a consultant to the Royal Navy. He was also a member of Departmental Committees on Prison Dietary and on Persistent Offenders. He has been President of the Society for Addiction, President of the Medico-Legal Society and President of the Psychiatric Section of the Royal Society of Medicine. He was a Vice-President of the 23rd Congrès de Médecine Légale, Paris, 1946, and also a Vice President of the International Congress on Mental Health, 1948. His publications include *Forensic psychiatry* (1927), *The medical aspects of crime* (1936), *The psychological treatment of crime* (jointly) (1939), *The adolescent criminal* (jointly) (1942), *Society and the criminal* (1949), as well as numerous papers in the medical journals, on crime and insanity.

DR. H. J. EYSENCK is the Director of the Psychological Department at the Institute of Psychiatry, and Senior Psychologist to the Maudsley and Bethlem Royal Hospitals. He obtained his Ph.D. degree from the University of London, and is a Fellow of the British Psychological Society, of the American Psychological Association, and a Fellow and Member of the Council of the Eugenics Society. His work has been mainly concerned with the psychology of personality, both in its abnormal and normal aspects; he has published extensively, also, in the fields of aesthetic appreciation and social attitudes. His best known work, *Dimensions of personality* (1947), describes large-scale experimental studies on neurotic and normal subjects, carried out during the war. His present work is concerned mainly with an extension of these studies to psychotic adult subjects and to normal and maladjusted children.

DR. MICHAEL FORDHAM is an analytical psychologist, who has been Chairman of the Society of Analytical Psychology and is the Director of the Society's Clinic. He is one of the editors of a forthcoming collected edition of Professor C. G. Jung's works. He has made a special study of child psychology and its relation to Jung's discoveries. He maintains that the archetypes of the collective unconscious can be demonstrated in the psychology of children, and amongst his publications is a book entitled *The life of childhood* (1944) in which he sets down the evidence for his views. He is at present Assistant Director of the Child Guidance Unit of the West End Hospital for Nervous Diseases.

DR. EDWARD GLOVER was trained in psychoanalysis under the late Karl Abraham of Berlin. Settling in London in 1922, he played an active part in the development of the Institute of Psycho-Analysis and of its London Clinic, of which he was for many years Director. He also organized much of the research activity of the British Psycho-Analytical Society. For a time he was Secretary of the International Psycho-Analytical Association. He was also one of the founders of the Institute for the Study and Treatment of Delinquency. An authority of international repute on the theory and practice

of psychoanalysis, he has published many books and numerous research monographs on these subjects. His most outstanding research contributions include the "nuclear theory" of ego-development, and an investigation of the causes of war, *War, sadism and pacifism* (1947). He is also the author of *Investigation of the technique of psycho-analysis* (1940) and of a general handbook on the subject, *Psycho-analysis* (1949).

DR. DENIS HILL is physician in Psychological Medicine to King's College Hospital, London. He is also physician to the Department of Applied Electrophysiology at the Institute of Psychiatry, Maudsley Hospital, London, and assistant physician to the corresponding department at the National Hospital, Queen Square. For ten years he has made a study of the application of electroencephalography to the problems of psychiatry. His published work includes a chapter on the epilepsies in Sargent & Slater's *An introduction to physical methods of treatment in psychiatry* (1948); "Cerebral Dysrhythmia: its Significance in Aggressive Behaviour" (*Proc. R. Soc. Med.* 1944, 37, 317), and "Electroencephalographic Studies of Psychopathic Personalities" (*J. Neurol. Psychiat.* 1942, 5, 47). With Watterson, he suggested that many of the minor anomalies found in the electroencephalograms of neuropsychiatric patients are due to defective maturation in the central nervous system.

DR. EMANUEL MILLER is physician and lecturer in Psychopathology at the Maudsley Hospital and physician in Child Psychiatry at St. George's Hospital, London. He is also Co-Director of the Institute for the Scientific Treatment of Delinquency, a Fellow of the Royal Society of Medicine and of the British Psychological Society. He has been physician at the Tavistock Clinic and Senior Psychiatrist to the West End Hospital for Nervous Diseases, London, and in 1926 he established the first child guidance clinic in Great Britain. During the war he was a lieutenant-colonel in the RAMC, worked on the War Office Selection Board, and later did research work in the War Office Department for Neurological Research and Statistics. Amongst other works, he has written *Neurological psychotherapy* (1926); with other authors, *Neuroses in war* (1940); and has edited *Growing child and its problems* (1937).

MR. CYRIL F. PENTON is an authority on the law relating to mental health. He has had twelve years' service with the Board of Control (Lunacy and Mental Deficiency), and is its Legal Senior Commissioner. Mr. Penton was educated at Eton and at Trinity College, Cambridge, and in 1942 he was made an honorary member of the Royal Medico-Psychological Association.

DR. FELIX POST qualified from St. Bartholomew's Hospital in 1939 and after general hospital work received his psychiatric training at the Mill Hill Emergency Hospital and at the Royal Edinburgh Hospital for Mental and Nervous Disorders. Following service with the RAMC as psychiatric specialist, in 1947 he was appointed assistant physician to the Maudsley Hospital, London. He is a member of the Royal Medico-Psychological Association and of the Royal Institute of Philosophy. His published work includes studies on mental patients over the age of 60 (*J. ment. Sci.* 1944, 90, 554) and on psychiatric illness in coal miners (*J. ment. Sci.* 1946, 92, 574).

DR. J. R. REES is a psychiatrist whose main interests have lain in the problems of the psychoneuroses and in the sociological approaches to mental health. He was one of the original staff of the Tavistock Clinic and later became its Medical Director. During the recent war he served for six years as Consulting Psychiatrist to the Army. He is at the present time President of the World Federation for Mental Health. Dr. Rees is the author of several publications, including *The health of the mind* (1936) and *The shaping of psychiatry by war* (1945).

DR. DEREK RICHTER is Director of the Neuropsychiatric Research Centre at Whitchurch Hospital, Cardiff and lecturer in Neuropsychiatry in the Welsh National School of Medicine. He qualified originally as an organic chemist at Oxford and then worked for some years with Sir Frederick Gowland Hopkins at Cambridge. His earlier work was mainly in pure chemistry, but at Cambridge he worked on enzymes and on endocrine action. His research on adrenaline and acetylcholine led him to develop a special interest in the nervous system, which he studied with Professor Golla at the Maudsley Hospital, London. Later he completed his medical qualification at St. Bartholomew's Hospital and during the war he was attached to the Neurosis Unit at Mill Hill Emergency Hospital. His recent research has included investigations on anxiety, on ageing and on the biochemical changes in the brain in emotional states. His publications include "Recent Progress in Psychiatry" (*J. ment. Sci.* 1944, 90, 74) and "Biochemical Aspects of Anxiety" (*Proc. R. Soc. Med.* 1945, 38, 674).

DR. W. CLIFFORD M. SCOTT is Medical Director of the London Clinic of Psycho-Analysis and lecturer in dynamic psychology at the Institute of Psychiatry, University of London. As a pupil of Professor Adolf Meyer (Johns Hopkins) and the late Professor C. Macfie Campbell (Harvard) he came to England to train with the British group of psychoanalysts. He has been connected with the psychoanalytic treatment of manic-depressive and schizophrenic psychoses. Apart from the psychopathology of psychoses, his chief work has been in attempting to link the "body image" concept of neurology to psychoanalytic concepts and ego development. He is the author of a number of articles which have appeared in medical and psychological journals.

DR. P. E. VERNON is Psychological Research Adviser to the Defence Services and the Civil Service Commission. He was educated at Cambridge University and worked there, and at Yale and Harvard, from 1927 to 1933, chiefly on the psychological study of personality and temperament, and on the psychology of music. After some experience of child guidance and of the training of teachers, he became head of the psychology department in the University of Glasgow from 1939 to 1947. During four years of the war he worked in the Admiralty and War Office personnel selection departments on construction and validation of psychological tests, and on other psychological and statistical studies of the abilities of recruits, selection and training methods, etc. He is the author of *Measurement of abilities* (1947); *The assessment of psychological qualities by verbal methods* (1939); *Studies in expressive movement* (with G. W. Allport) (1933), *Personnel selection in the British Forces* (with J. B. Parry) (1949); and of some fifty psychological tests and articles.

## THE INTERNATIONAL CONGRESS ON MENTAL HEALTH

London, August 1948

J. R. REES C.B.E. M.A. M.D. F.R.C.P.

*President, World Federation for Mental Health*

*Hon. Physician, Tavistock Clinic, London*

*Hon. Consulting Psychiatrist to the Army*

- 1 First post-war congress
- 2 Mental Hygiene Conference
- 3 Statement of the International Preparatory Commission
- 4 Other activities
- 5 Results of the Congress

It may seem somewhat strange that a report on the Congress on Mental Health should introduce a symposium of scientific contributions. But as this number of *British Medical Bulletin* was originally planned with reference to the Congress and with the intention of giving participating members a survey of mental health work in Britain, it is not inappropriate that some note about the activities and results of the Congress should be recorded here.

### 1. First Post-War Congress

In the first place, it is worth noting that this large gathering of some 2,200 people concerned with questions of mental health was the first large-scale meeting of the kind called since the recent war. Fifty per cent of those attending came from overseas, from 54 countries, so that between 11 and 21 August 1948 a great many new contacts were made between workers from the various countries, and a very large number of old contacts and interests were renewed. Most unfortunately it proved impossible to find accommodation for the Congress in Oxford or Cambridge, so that we had to work against the difficulties and distractions of a large meeting in the centre of London.

Almost immediately after the end of the war, we in Great Britain were asked by three separate sponsoring international groups to arrange their next conferences in this country. Those bodies, the International Committee for Mental Hygiene, the International Committee for Child Psychiatry and the International Federation for Medical Psychotherapy, were obviously concerned with an overlapping group of scientific workers, so that we decided to run the three conferences consecutively, combining them into one Congress. Thirty months of planning and preparation were in fact not too long.

Comparatively little need be said about the Conferences on Child Psychiatry and on Medical Psychotherapy. For the most part they were orthodox conferences and the themes selected for them—"Personality development with special reference to aggression" and "Guilt"—stimulated the production of a number of excellent papers, though as foreseen it was difficult to have effective discussion with such large meetings. The second and third volumes of the Proceedings<sup>1</sup> of the Congress, which have recently been published, will be found to give a very complete record of these two conferences.

### 2. Mental Hygiene Conference

From the ideological angle and as an experiment in international co-operation, the week of the Mental Hygiene Conference provided a good deal more interest. The Organising and Programme Committees had from the first been concerned to arrange a meeting which would be stimulating and which would have some special relevance to the times in which we live. It was determined that for once the conference should in large measure break away from familiar procedures and that we should try to tackle the rather timely subject of applying our various skills in the mental health field to "sick groups", to communities and to national tensions, rather than limiting ourselves to the day-to-day developments of psychiatric and mental health work.

The mental hygiene movement has always emphasized the necessity for team work and the recent war has firmly underlined the importance of interprofessional co-operation in the field of mental health. Psychiatrists may indeed have to play a central role in all prophylactic planning just as in treatment, but psychologists, sociologists, educators, anthropologists, clergy and political scientists all have their contribution to make as people who are concerned with the understanding and welfare of human beings. For the Conference on Mental Hygiene we therefore chose as a dominant theme, "Mental health and world citizenship", and we then attempted to prepare for the conference so that it might in fact be a co-operative group activity, rather than a number of people passively listening to papers however thoughtful or well prepared.

Preparatory Commissions or discussion groups, which for the most part were interprofessional, were started in many countries and worked hard on the various aspects of this wide theme which made a special appeal to them. The final decision as to the topics for the plenary sessions of the Conference was not made until it became clear what the principal interests of the whole participating group were likely to be. This ambitious plan was both a success and a failure. It may be said to have failed because in fact there was not sufficient time for many of the groups to learn to work together and then to produce studies and factual material that were new. Many of them worked for a year and no doubt would have been glad of two years before making their reports. The groups did something of importance, however, in that they brought together, in many academic centres and other places, workers in the different professional fields who had never even met each other, far less worked together or made any attempt

<sup>1</sup> [Proceedings of the International Congress on Mental Health, London, 1948  
4 vols., H. K. Lewis & Co. Ltd., London, 1949.—Ed.]

previously to weld their ideas for the attainment of a common objective. Having done this, a great number of these groups are continuing to work together and some at least will become significantly productive in the future. Perhaps there was some justice in the remark of one commentator who described this as "the first large scale 'combined operations' by social scientists on a world level for the benefit, perhaps the survival, of mankind as a whole."

It may be said, therefore, that the Congress on Mental Health began its scientific work at least a year or more before August 1948; by early June 1948 over 300 reports had been sent in from national interprofessional groups with a membership of approximately 5,000 in 27 different countries. All the main divisions of the Conference theme were covered—"World citizenship and good group relationships"; "The individual and society"; "Family problems and psychological disturbance"; "Mental health in industry and industrial relations"; and "Planning for mental health; organisation, training, propaganda." Many of the documents sent in were of great value and we hope that they will be made available in their original form. So far as the Conference was concerned, however, an effort was made to co-ordinate and integrate these various reports; editors in Holland, USA and Great Britain set to work and produced carefully summarized reports, in sections, for the use of those who were to make the main communications to the plenary sessions, and for the consideration of an International Preparatory Commission, which met before the Congress.

### 3. Statement of the International Preparatory Commission

This International Preparatory Commission was composed of some 25 people from 10 different countries, representing long experience in some 10 professional disciplines, who lived and worked together for a fortnight in the country outside London. As a result of their very strenuous work, they produced an agreed *Statement*<sup>2</sup> covering the whole subject. This was no light task. Multi-professional thinking on topics of this kind is not just a matter of compromise or a statement of different points of view; some attempt has to be made to integrate the different approaches and produce something which might be called a new concept.

The *Statement* is extremely interesting. It clearly could have been made far more definite and perhaps more readable had it been the work of one person, but it is a quite remarkable document when one considers its origin and that it carries the agreement of so many people who were experts in their own particular fields. This international group suffered from the fact that there were no representatives either of Eastern Europe or of the Far East present, despite our efforts. The group were fully conscious that allowance would have to be made for this fact, and the difficulty of producing a statement which could be made applicable to countries with quite different cultural aspects was realized. The *Statement* was printed just in time for the Mental Hygiene Conference and was distributed to every member. Sections of it were discussed at length by some 20 or more

international discussion groups formed of Congress members and in turn their comments were submitted to the Conference and have been printed in the bulletin of the Congress. When the *Statement* was submitted for general approval to the whole conference of 2,000 members at the last session, it was accepted with only one dissenting voice.

The *Statement* is interesting in its emphasis upon "the modifiability of human behaviour throughout life, especially during infancy, childhood, and adolescence, by human contacts. Examination of social institutions in many countries shows that these also can be modified." Later it says:

Men have long accepted the inevitability of recurring misfortunes in the shape of group conflict and war on the grounds that 'that is human nature'. This belief has even been used to maintain the existing state of affairs. When, however, social and psychiatric science had progressed sufficiently, the rigorous investigation of 'human nature' clearly revealed that these discouraging traditional views had no valid foundation . . .

Man and his society are closely interdependent. Social institutions such as family and school impose their imprint early in the personality development of their members, who in turn tend to perpetuate the traditional pattern to which they have been moulded. It is the men and women in whom these patterns of attitude and behaviour have been incorporated who present the immediate resistance to social, economic and political changes.

Thus prejudice, hostility, or excessive nationalism may become deeply imbedded in the developing personality without awareness on the part of the individual concerned, and often at great human cost.

Perhaps the most important contribution of the social sciences in their joint approach to the urgent problems facing mankind is the recognition of the plasticity of human behaviour and social institutions and of the resistance of each to change.

The final paragraph before the recommendations concludes:

There is no room here for any easy optimism. Men's hopes for world peace have been shattered so often in the past, that we would be doing a disservice to humanity if we did not fully recognize the difficulties which must still be overcome. Nor can we take it for granted that the insights gained by psychiatrists and social scientists will necessarily be employed in the interests of a world community. Just as the discoveries of the physicist can be used to construct or to destroy, so too the psychological sciences can either contribute to mental health or they can be exploited to divide and confuse mankind. It is only with a full awareness of these and other obstacles that we can do our work with any prospect for success. There is, however, all the difference between recognizing that a task has immense difficulties, and insisting that it is impossible.

This then, as we see it, is the ultimate goal of mental health—to help men to live with their fellows in one world.

The *Statement*, which was adopted by the Congress, includes a considerable number of recommendations to be sent on to United Nations and to their specialized agencies, UNESCO and the World Health Organization. It is satisfactory to learn that action is already being taken by these agencies on a number of suggestions put forward by the Congress.

### 4. Other Activities

While the whole Conference was discussing this main theme through its small international groups and in plenary session, a considerable number of meetings was held in various parts of London, designed for those with special interests in certain branches of psychiatric and mental health work which were not specifically related to the main theme.

For generations the impact of medicine on psychology was almost exclusively clinical and in the main confined to the use of psychological ideas and methods for the diagnosis and treatment of mental disorder. It was considered right and fitting that the medical student, if he learned any systematic psychology at all, should have his introduction to this subject at a late stage of his training, and by direct contact with patients in hospital or in private practice.

#### 1. A Remarkable Change

The last eight or nine years have seen a very great change. The view expressed above is now, almost everywhere, regarded as unsound and unnecessarily biased. In this country every authoritative report on medical training which has lately been made public has insisted upon the necessity for the provision of early teaching in psychology

for all medical students. Moreover it is recognized that such teaching ought to be essentially scientific and as far as possible experimental, and that it should be accompanied by a reasonable instruction in the use of statistics.

More immediately important still, perhaps, the range of psychological research and investigation in regard to mental health problems has been enormously extended and their directing ideas revolutionized. No longer does the mentally defective individual, the psychopath, or the eccentric attract almost exclusive attention. By far the greatest amount of effort is devoted to the establishment of scientifically attested knowledge about how to keep the normal person healthy in the face of all the strains and stresses of modern life which he must inevitably meet. It now seems clear that mental health is something that should be established and preserved, and not something to be broken down and then re-established.

Many influences have contributed to this striking change. The temper of the times is predominantly scientific. Everybody recognizes that man's greatest triumphs in the world of nature have been won by the development of exactly controlled methods of observation and experiment. At the same time it is universally acknowledged that control over nature may be used as readily to man's disadvantage as to his advantage. It no longer appears sensible to try to counter this difficulty by speculative theory, or to allow the disadvantages to occur and only then to try to deal with them. The same methods that have been used to extend man's power over materials must now be used in an effort to direct his enhanced opportunities, not only so as to avoid individual and social breakdown, but positively to promote human well-being.

More specifically, many of the most outstanding applications of scientific invention and discovery during the Second World War led to an enormous increase in the use of machines of all sorts. These set their operators new problems and imposed upon them new strains, often of a very severe nature. To solve the problems and alleviate the strains there grew up a new type of scientific investigation known generally as "personnel research", of which the best summary published account is in a Medical Research Council report (1947)<sup>1</sup>. The broad aim of this type of work was to control the design of instruments and to direct the conditions of their operation so as to bring both as completely as possible within the range of variations of the normal bodily and mental equipment of the operators.

#### MENTAL HEALTH CONGRESS

*Continued from page 6*

These meetings were for the most part very successful and stimulating, and without doubt some members found it a relief to get down to the discussion of a more localized and concrete topic after the effort to encompass the main theme with its vastness and urgency.

There were other activities in progress also. The delegate meeting of the Child Psychiatry Conference resulted in the formation of an International Association for Child Psychiatry (President, Dr. Frederick H. Allen of Philadelphia), whilst the delegate meeting called by the International Committee for Mental Hygiene met at the Ministry of Health and launched a World Federation for Mental

Health, which has, since the Congress, been accepted as a non-governmental body with consultative status by both UNESCO and the World Health Organization.

#### 5. Results of the Congress

If one may therefore sum up the work carried through in London last August and through many months preceding, one might say firstly, that a stimulus has been given to interprofessional team work for mental health; and secondly, that certain new concepts have begun to be formulated as to the contribution that psychiatrists and social scientists of all types may hope to make towards the solution of the wider prophylactic problems in the field of mental health. It remains to be seen whether the hard work put in by so very many people will produce recognizable results in the future.

Within reason it was remarkably successful and it is the continuing influence of this movement for "personnel research" which has very largely brought about the new direction of approach to problems of mental health in civil life.

At the same time the swift growth of experimental medicine, particularly in the fields of chemotherapy and nutrition, the emergence of the rather inaptly named "social medicine", and the specific development, especially in Great Britain, of industrial medicine have played exceedingly important parts in effecting the same change of attitude. Moreover the astonishing results of physical methods of treatment of certain rather desperate forms of mental disorder have certainly had not a little to do with the present active exploration of experimental technique in the study of mental health. These influences have securely tied up with medical science a movement which, without them, could quite easily have been treated as a specialized branch of experimental psychology alone.

Even a brief and general survey such as the present one would be incomplete without reference to influences spreading from the "mental test" movement. From very early days there have been prominent psychologists whose principal interests have lain in the development of methods for the study of individual differences. Some of the most effective contributions have been made by English-speaking investigators, especially in Great Britain, through the pioneer work of the late Professor C. E. Spearman, of Sir Cyril Burt and of Professor Godfrey Thomson. These have in practice issued in the belief that for most, if not all, of the vocations available in a modern society there is what may be called a "fit" mental and bodily constitution. Tests, which are essentially diagnostic and prognostic devices, are designed to indicate, and perhaps to measure, this fitness. They can then be used in the service of mental health both to select fit people—who will thus be the more likely to retain normal health as they pursue the vocations for which they have been chosen—or to diagnose the nature of "unfitness", and to effect a reasonably exact prognosis at any stage of treatment. The test development, grown now to tremendous size, has had considerable repercussions on the more traditional clinical aspects of the study of mental health.

This is the general contemporary setting as it is to be found in Great Britain. Let us now consider a few specific illustrations of current trends.

## 2. Experimental Developments

### *a. Problems of Display and Control*

A very large proportion of the population of any large modern state is concerned with the day-to-day manipulation of machines of some kind. The operator of every machine is set two classes of problem. He must be able to interpret, within limits of accuracy and usually at speed, the signals for action which the machine gives, and he must be able to manipulate the controls which are provided. If the signals are badly designed—small or excessively large, crowded, ill-shaped, inconveniently timed, awkwardly placed, easily confused with others—the operators will suffer unnecessary strain, the cumulative effects of which are very likely indeed to produce accidents, dissatisfaction and anxiety, troublesome and avoidable fatigue, and, it may be, various forms of specific or general disease. All these and many other of

the variable characters of signals for action constitute problems of display. They obviously invite an experimental approach which will set out to discover the normal limits of variability of the human activities involved that are consistent with their efficiency in continued exercise. If the work signals can be designed to lie within those limits one of the necessary steps towards restricting the chances of mental ill health in the ordinary citizen will have been taken.

Precisely similar problems arise in the case of machine controls. Many designs of controls which are entirely satisfactory from an engineering point of view present very great difficulties to the operator. A solution of problems of display demands a much more firmly based knowledge than we have at present about the basic activities of the special senses, especially in relation to one another, and of the associated processes of human judgement. To solve the parallel problems of control we need fundamental experimental studies of the nature of bodily and mental mechanics.

The great bulk of the possible applications of these ideas to civil and peacetime occupation has yet to be worked out. But the methodology and the broad problems remain the same in peace as in war and already much has been learned about display and control for the airman, the sailor, the navigator and for many kinds of operations which involve the tracking of targets. Various organized groups of workers in Great Britain are now actively attempting to approach the many pressing peacetime problems in this field. (Cf. Craik, 1944; Fitts, 1947; Morgan, 1947.)

### *b. Problems of Continued Exercise*

People get tired. There is no doubt about that. When they do, it is usually considered to be either because they have to keep on doing the same things over and over again for long periods, or, also for long periods, they have to switch from one thing to another without rest. This is much more doubtful. The precise study of the changes in human activity which may be traced to the continued exercise of that activity has always been of psychological importance, but never more so than now. For it has become a matter of popular belief that fatigue is both inseparable from modern conditions of life and work and also is a potent cause of mental ill health. It seems as if the increased speed of modern life, largely consequent upon the widespread applications of scientific invention, its enormous and often narrow specialization, and the tremendous amount of planning, which has the effect of making routine the daily activities of immense numbers of people, all increase the liability of the general population to fatigue.

It should be more widely known than it is, that there is much evidence that—always excepting work involving heavy and continued muscular effort, and providing that working conditions (including display and control) are devised with a proper regard for what most folks can do readily—work can be continued for very long periods indeed with no bad effects whatsoever, either immediate or remote. If, in special cases, it can be shown that relatively light work does produce hampering fatigue, it is almost certain that this is due to faulty design and in particular to some form of accumulated anxiety which goes with this. All these are topics of very active current research; further discussion is given by Davis (1948).

*c. Problems of Tolerance Limits*

It is a reasonable hypothesis that for almost all directions of human activity there are limits of toleration, both environmental and internal, the persistent passing of which leads to mental trouble. All regularly exercised human functions have been built up in a world of change. Even wide changes within limits impose no important variations in the efficiency or ease of work. But outside these limits small changes may mean big deteriorations. Moreover, in spite of individual differences, the limits remain remarkably consistent for all healthy individuals, given the adaptation which is secured by appropriate training and exposure. For example, a wide range of human functions begin to break down badly at an effective temperature of some 85 to 90° F. There are similarly determinable limits of tolerance for cold, for speed of work, for numbers of operations requiring simultaneous regard, and for many other conditions. To know where these limits are set, and to what extent they can be safely ignored when special spurts are required, are two of the principal practical concerns of current studies undertaken in the interests of mental health (Mackworth, 1948).

*d. Problems of Incentive and Motivation*

Everybody recognizes that the maintenance of health, both bodily and mental, depends largely upon the reasonable exercise of a wide range of normal human functions. Such exercise will not usually be undertaken in the absence of adequate prompting and directing conditions, external and internal. Broadly, the external prompting conditions are regarded as belonging to the order of incentives and the internal ones to that of motivations.

Beyond question much in the study of incentive and motive lies outside the experimental field at present. In particular the incentives and motives of practical life have an urgency which it is very difficult to reproduce under experimental conditions. But it is probable that the ways in which they operate and the general methodology of their study do not change directly with their intensity. Already, for example, it has become clear that experiment can contribute valid and important evidence about the characteristic ways in which forms of encouragement and discouragement (including specific rewards and punishments) operate; and about the effects of targets of performance, definition of tasks, competition, and even particular types of leadership. Further, current experiments are throwing much light upon those widely applicable motives which depend on a knowledge of the results of performance, and upon signals provided during performance which indicate the difference between what is done and what is desired to be done. Especially the limits of incentive and motive are being worked out: the difference between those that produce spurt results and those that maintain persistent improvement or deterioration; the relation of both to tolerance limits; and how and why both have their most marked effect upon performers who, even without them, show the greatest relative efficiency. In one way and another it seems certain that one of the most fruitful current trends is that which may lead to the clarification, by controlled methods, of the many problems of incentive and motive, and to a sound knowledge of how these influences work.

(See Elwell & Grindley, 1938; Carmichael & Dearborn, 1947; Mackworth, 1947.)

*e. Problems of Ageing*

Nearly every civilized community is now facing the very serious problems of mental health which are associated with a steadily increasing average age of its working population. The outstanding questions which demand well-founded answers are:

- i. What are the characteristics of the continued exercise of skill, with or without muscular effort, which mark advancing age?
- ii. Within what chronological age-ranges do these changes first become significant?
- iii. What methods can be developed which will show not only the level of over-all performance of whatever skill is selected for study, but also the level of performance of its constituent items, and their internal relationship?
- iv. Are satisfactory methods of training (or of re-training) different for different age-ranges if the main criterion is the avoidance of dangerous mental strain? (The current approach here characterized to problems of ageing is best represented by the work of the Nuffield Research Unit of the Psychological Department of the University of Cambridge. Published reports of this will be available in the near future.) (Cf. Welford, 1949.)

*f. Problems of Special Disability*

Finally, in the general experimental field, there is a marked increase in the study of special disabilities. This is due, in the main, directly to developments of industrial medicine and of education. The former has greatly stimulated the investigation of psychological aspects of specific industrial diseases, with emphasis upon prevention and rehabilitation. The latter has led to a rapid growth of research into the psychological concomitants of partial disablement, especially of deafness and blindness in children.

**3. Clinical Developments**

Only a very biased view could pretend that any but a limited range of mental health problems can at present, or perhaps ever, be solved by controlled experimental procedure. Clinical and experimental methods have, in fact, to be developed side by side.

*a. Tests*

Tests are essentially diagnostic and prognostic devices. By them we attempt to find specific situations, performance in which will, within limits of statistical validation, predict the most probable performance in different but more or less related situations. Their function is exactly that of other diagnostic signs used by the medical man except that they aspire to an objectivity of scoring and interpretation which sets them as free as possible from any idiosyncrasies of the clinician.

Psychological tests for mental health purposes are being widely exploited now in three main directions. First,

on the assumption that people will be more healthy if they do the things for which they are by constitution most fit, to select them for their vocations in life. Successful as this enterprise frequently is, it is by no means the simple task that it is often supposed to be, or that it is frequently made to appear. In particular the follow-up procedures, which alone can justify the wide application of tests for this purpose, are still very much in their infancy. Second, psychological tests are used directly to clarify and assist the diagnosis of mental ill health, and to help prognosis at any stage of treatment. In this function they determine the main activities of the clinical psychologists who are, to an increasing extent, accepted as regular members of medical units attached to hospitals, clinics and special schools. Third, in conjunction with developments of statistics, psychological tests are being used in an attempt to carry out fundamental analyses of the human mental constitution and to detect the number and interrelations of its contributory elements. This is a very highly technical study, requiring far more critical insight and knowledge in regard both to the collection of data and to the selection of appropriate statistical methods than are commonly either realized or appreciated.

#### b. Questionnaires, Opinion Studies and Surveys in General

A great many problems of mental health depend upon the relation of individuals and groups of individuals to their social and cultural backgrounds. What, for example, is the precise effect of different systems of industrial management, of joint consultative bodies and the like? What are the differential results of different working shift systems, or of popular beliefs about wages, or promotion, or leisure time and its activities? Why are there unwanted occupations, and what are they? How does the enormous speed of mass intercommunication in the modern world affect public and private stability? There is almost no end to the questions of this kind that can be raised. In most cases experiment can hardly touch them, or can offer only very dubious and long-term results indeed. To deal with them, a very large variety of devices, such as questionnaires, opinion studies and social surveys, has been put forward and used. Most of these grew up in the USA but they are rapidly travelling to every large social group and they

represent a strong current trend in Great Britain. They involve far more, and more complicated, difficulties than can be discussed here. All that can be said is that they are often associated with promises which greatly outrun any reasonable chance of early achievement. While no fair-minded review of present tendencies can dare to neglect their rapidly growing importance and value, they are singularly unsuited to exploitation by people with little and superficial training who are on the look-out for quick results. Of the extensive literature available on these general topics, the most useful methodological book is edited by Cantril (1944), and a more comprehensive and theoretical treatment is made by Cantril & Sherif (1947).

#### 4. Implications

Any summary statement of the implications of these and other current trends in the psychological study of mental health must be tentative and hypothetical. It is extremely likely that results will differ from one social group to another and they will of course be partially determined by events which nobody can yet foresee. There is for example sharp cleavage of opinion between those who predict that mental health will remain the concern of the qualified medical man, though with specialized and far more scientifically directed psychological training than he has ever received in the past, and those who predict that the psychologist as such, without what is now regarded as the essential medical qualification, will become an indispensable member of every medical unit, with status and reward in all respects equivalent to that of the doctor. On the whole the latter appears to be the present trend in the USA and the former in Britain; but not unequivocally in either case. What is already sufficiently certain, in this country, is that the medical man of the near future will have a psychological training more scientifically directed, earlier, more persistent, and eventually, in suitable cases, far more broadly specialized than has ever been the case before. And at the same time all lively centres of psychological teaching and research will be forced to study problems and methods that will take them far beyond the confines of the lecture room and laboratory into the daily life, activities and aspirations of people everywhere.

Educational psychology falls into two main branches—the study of the mental differences between individual children and the study of the effects of different methods of training. Of these two branches the former has made the greatest progress, and possesses the most obvious implications for mental health. But the latter has given rise to numerous important researches, and has led to several unexpected discoveries. The distinctive characteristic of both branches consists in the scrupulous adoption of scientific techniques in place of the old-fashioned reliance on personal experience, traditional precepts, and unaided common sense.

For the most part the problems attacked and the methods employed have been dictated by practical needs. It is therefore hardly possible to appreciate the special contributions made by educational psychology without knowing something of its history.

### 1. The Development of Educational Psychology as a Science

Down to the closing decades of the 19th century, the psychology of education, like other applications of psychology, was regarded as proceeding essentially by deduction. Mill, for example, championed the view that the study of the mind was a department of natural science rather than of philosophy; but at the same time he insisted that experimental methods were unsuited to it (cf. Mill, 1856). The right procedure, so he declared, was “to formulate generalizations on the basis of common obser-

vation, and gather these into a consistent body of knowledge”. Admittedly, the knowledge so gained would be “only probable knowledge, not certain knowledge”. But, owing to the immature state of the ‘science of probability’ (or ‘statistics’ as we should now call it), little help could be expected from this direction.

It is amazing that Mill, the apostle of induction, should have entertained so sceptical a view of the possibilities of psychology as an inductive science. Yet, down to about forty years ago, when Stanley Hall’s *Adolescence*, Claparède’s *Pédagogie expérimentale* and Meumann’s *Experimentelle Pädagogik* appeared in quick succession, nearly every textbook on educational psychology was written in accordance with Mill’s principles. And his mode of approach is still commonly adopted in discussions of psychological problems by medical and educational writers who have had no training in modern psychology, and are therefore unaware of the rigorous techniques that are now available for verifying or refuting the conjectural inferences of the impressionistic observer.

### 2. The Application of Experimental and Statistical Techniques

The change began with the revolutionary proposals of Sir Francis Galton (1874, 1883). Galton held that individual psychology was “a self-subsistent department of anthropology—the science of man”. “It has”, he observed, “profound implications for philosophy and medicine, but is not itself a section of either.” As a science, it should, he argued, be treated as an inductive, not a deductive, branch of knowledge; and he set himself to demonstrate the applicability of both experimental and statistical procedures to its various problems. The direct result of his labours was the invention of experimental tests for assessing ‘natural ability’, and the introduction of mathematical devices, like the normal curve and the correlation coefficient, for standardizing and validating the results of such tests.

The implications of Galton’s work for education and for mental hygiene can hardly be better stated than in the words of one of Galton’s most eminent followers, William McDougall. “The corollary for the teacher”, he says, “is obvious. He must in future think less of the subjects he is teaching and more of the individuals whom he is endeavouring to instruct. The first essential is to discover the limitations imposed at birth by the child’s innate constitution; and the next is to adapt the system of instruction to the child’s capacities, not the child to the system of instruction. Only in that way can we hope to improve the intellectual efficiency, the mental health, and the moral well-being of the nation. Moreover, to do this with understanding, we must lay the foundations in an accurate knowledge of the mind of the growing child. As Galton has himself pointed out, no one can do this so well as the teacher; nowhere can it be done so readily as in the school.”

Indeed, Galton, as Pearson has remarked, “looked upon the school, not merely as an institution for educating the young, but as a laboratory for studying their mentality”. Galton himself observed: “As every hospital fulfils two purposes, to advance pathology as well as to relieve the sick, so every school might be made to fulfil not only the primary purpose of educating boys, but also the more urgent task of

promoting the science of education. Schools are ideal places for experimental and statistical inquiries."

Largely at the instigation of Galton, and with the willing co-operation of leading teachers, inspectors, and education officials, James Sully, Professor of Mental Philosophy at University College, London, founded in 1894 the Child Study Association. Its objects were "to encourage the scientific study of the individual child and the application of psychological methods to the problems of childhood, education, and school hygiene". In this way the child guidance movement was launched; and, thanks to the sympathetic assistance given by the Education Officer for London, Sir Robert Blair, and the Chief Inspector of Schools, Dr. C. W. Kimmins, it rapidly became a reality.

### 3. The Study of Individual Differences

The first step, in Galton's opinion, was for the teacher to make a systematic study of the capacities, needs, and limitations of every individual child. "By developing his potentialities to the utmost, and in the direction that is most natural, we shall not only make the most of our human resources, but avoid the fatigue, the strain, and the breakdown that is now so common in our schools." With this aim in view he drafted a school record-card. This was to be filled up for every pupil first on entrance and then on 29 February of every leap year. Its object was to exhibit in accurate and comparable form the physical, medical, mental and educational characteristics of each child, and his development and progress throughout the years of growth.

Children who were found to be "persistently backward, or showed signs of nervous strain or moral defects" were to be referred for fuller and more expert examination at a central office, such as the 'anthropometric laboratory' he had established. In London, for example, teachers began to refer their more difficult cases to inspectors with a psychological training, like Ballard and Winch, and were later instructed to nominate dull and backward pupils for possible admission to a special class or special school.

### 4. Diagnostic Methods

At the beginning of the present century, both teachers and school medical officers thought and wrote in terms of the old-fashioned 'faculty-doctrine', particularly in the form given to it by the phrenologists, who in Great Britain achieved a wide popularity during the 19th century; and when systematic research in educational psychology was first started in Britain, mental deficiency and 'moral imbecility' were still regarded as symptoms of organic defects affecting more especially the central nervous system, and revealing themselves by physical signs. Binet and Galton themselves began with the view that intellectual and moral qualities could often be inferred from bodily characteristics. As a reference to contemporary textbooks on mental deficiency will show, the diagnosis of deficiency in cases referred to medical officers for possible certification was based partly on an assessment of the size of the brain (usually by measuring the circumference of the skull) and partly on an inspection for anatomical 'stigmata' (especially the physical signs of the clinical types). The idea of measuring mental abilities by mental tests was considered to be at once impracticable and far-fetched. Even the

most enlightened writers on the subject held that at the very best "the applicability of the methods of the psychological laboratory would be exceedingly limited", and that they were "unsuited for use in the consulting-room or for diagnosing the conditions dealt with" (cf. Tredgold, 1914).

As a result of the methods then in vogue the special schools were filled partly with a small proportion of low-grade cases of well-recognized types, many of them ineducable imbeciles, and partly with a large number of retarded children who, in the view of teachers and magistrates, were not mentally defective in the technical sense. Indeed, after two or three years of training, a considerable proportion were actually returned to the ordinary school as 'cured'. Parents complained of the stigma, teachers of the mixed classes they had to deal with, and the education committee of the expense. Eventually in 1913 the London County Council appointed an educational psychologist, as a member of the school inspectorate, to deal not only with this particular difficulty, but with any psychological problem arising out of the work of the schools.

An incidental result of this appointment was that many London schools became what Galton had desired—laboratories for the systematic investigation of educational problems by scientific procedures. Research students, who had been trained at one of the departments of psychology of London University and who were themselves as a rule teachers of some experience, co-operated with the Council's psychologist in carrying out a long series of educational investigations. Thus gradually a fairly comprehensive scheme of child guidance was built up.

### 5. Classification

In the early days of this work, interest chiefly centred on the discrimination of the subnormal. The first problem therefore was that of classification. The faculty-doctrine had brought with it the doctrine of discrete types; and the medical and legal definitions of 'mental defectives' and 'moral imbeciles' were expressed in terms of the type-doctrine: each group was supposed to consist of a distinct and clearly recognizable pathological class. On the other hand, academic psychology was strongly opposed both to faculties and to types; and early work with mental tests seemed at first to support its objections.

Once again it was Galton who indicated the solution. Although the alleged types overlap and merge into one another without any clear lines of division, this does not prevent us from accepting a classification according to complex patterns or tendencies. Accordingly, following out Galton's suggestion, Pearson (1902) proposed a statistical technique for investigating the 'index characters' or 'syndromes' on which a working classification could be based.

*Factor-analysis*, as this technique has since been called, has thrown a flood of light on the structure of human personality, and has produced a convenient scheme or schedule for investigating the characteristics of any individual personality—whether subnormal cases needing educational guidance, like the backward, neurotic, defective, or delinquent; or normal or supernormal cases put forward for vocational guidance or allocation to particular types of school.

Broadly speaking, mind or personality is regarded as being composed of both 'general' and 'specific' factors, not unlike the mental *genera* and *species* of the schoolmen. Of the general factors, the most important are (i) the factor of innate general intellectual ability, usually called intelligence, and (ii) a corresponding factor of general emotional instability. On the cognitive side, the specific or group factors include (a) *formal* factors like perception, memory, reasoning, and the like, and (b) *content* factors such as the verbal factor, the numerical factor, the spatial factor, and the various factors underlying imagery of different types (visual, auditory, kinaesthetic, and so forth). So far the scheme agrees admirably with the doctrine of a hierarchy of nervous levels as taught by Hughlings Jackson (1899), Sherrington (1906), and Head (1920). On the emotional side the chief group factors point to a classification not unlike that embodied in the traditional theory of temperaments. The so-called temperamental factors are thus responsible for physical, physiological, and biochemical differences, as well as for differences in disposition and character. The notion that emotional types can be determined from body-build—a notion widely popularized by the followers of Kretschmer, Berman, and Sheldon—has been shown to contain an element of truth. The correlations are usually positive, but are much too low for practical use.

## 6. Causes

Early work on subnormal children directed attention mainly to those causal influences that were at once conspicuous and amenable to treatment. Social reformers stressed social conditions, school doctors physical conditions. Reports of Care Committees emphasized the ill effects of poverty, overcrowding, lack of cultural opportunities; medical officers' reports pointed to the frequency of malnutrition, infectious fevers, septic tonsils and adenoids, defective sight and hearing, disturbances of the endocrine glands, and alleged organic defects of the nervous system (congenital lesions of the brain, chorea, epilepsy, petit mal, and the like). Pearson and the eugenists have argued in many publications that these had comparatively little influence, and that the child's heredity was chiefly to blame. The psychoanalysts agreed in minimizing the importance of organic and economic conditions, but placed the chief weight on unconscious emotional factors developed during early childhood.

Such controversies could be solved only by careful statistical inquiries. Psychological work has amply demonstrated that, although physical and economic conditions may play their part, the main determinants are mental. Multiple causation is the general rule. Different causes are responsible in different cases; and nearly always not one influence but a number are at work.

## 7. Inheritance of Mental Characteristics

What the educationist wants to know, first of all, however, are the innate characteristics of each pupil, and how far the child's inborn or inherited limitations are likely to defeat or to restrict the effects of education. The investigation of heredity has proved far more complex than was originally supposed. The majority of traits appear to follow a multi-factor inheritance; a few defects seem due to uni-factor

inheritance. There is now little question that the general factor underlying cognitive efficiency is in the main inherited, or (as the geneticist prefers to put it) "attributable to the potentialities of the child's genetic constitution". Hence intelligence is now commonly defined as innate, general, cognitive efficiency. However, although the aim of intelligence testing is to measure the child's innate ability, it cannot do so with absolute precision; and (contrary to common opinion) no competent psychologist trusts merely to a mental age or I.Q. as obtained with the Binet scale or with written 'group tests.' The family history and the child's early development have always to be explored before a diagnosis of mental deficiency can be safely pronounced in any doubtful or borderline case; and a full course of training is essential before the practical psychologist can venture to apply and interpret such tests in individual cases.

In spite of the strong opposition put forward by Spearman (1927), much evidence has been accumulated to show that many special abilities and disabilities may be, in part at least, innate. Nevertheless, in most cases, provided the child's intelligence is normal, the majority of the difficulties can be compensated for, or overcome by appropriate methods of training.

The factor making for temperamental instability ('general emotionality', as it is commonly called) appears also to be largely innate, and is no doubt responsible for the notion of a 'neuropathic diathesis' described by many medical writers. In the older medical textbooks on mental deficiency, a condition called 'moral imbecility' was also recognized, and attributed to an innate deficiency in the so-called 'moral sense'. A similar conception formed the basis of Lombroso's theory (1907) of the 'born criminal' (*il reo nato*). Later investigations have indicated that such a view is exceedingly misleading. There is no such faculty as the 'moral faculty' or 'moral sense'. Morality and criminality are acquired. Criminal habits and moral defects, like intellectual backwardness and educational deficiency, are due to a large number of differing causes. Indeed, temperamental characteristics seem even more amenable to environmental influences, whether for good or for ill, than intellectual characteristics.

## 8. Mental Tests

Standardized tests are now available for measuring the mental and scholastic abilities of boys and girls at every age of their school career. In the interests not only of the community, but also of the individual himself, it is essential that each child should be educated according to his aptitudes and needs. Psychological tests have consequently been employed, not merely to diagnose cases of certifiable deficiency and to pick out the dull and backward, but also to discover the bright and the supernormal, and the pupil with exceptional gifts or talents. In London from the earliest years the work of the educational psychologist was concerned with devising reliable means of allocating older pupils to schools of special kinds—secondary (or 'grammar') schools, central schools, trade schools, arts schools, and other types of commercial or technical institute. This has led to ingenious suggestions for measuring verbal ability, mechanical aptitude, artistic capacity, and the like.

The success that attended the construction of intelligence tests has encouraged psychologists to try devising analogous tests for temperamental and moral qualities, or, as they are sometimes termed, 'personality traits'. Measurements of physiological characteristics—pulse, blood pressure, cutaneous circulation, metabolism, differences in autonomic activity and endocrine secretion—have so far proved disappointing. The paper and picture tests, so popular with amateur psychologists in all professions, have proved to possess very little diagnostic value in individual cases. In spite, therefore, of the claims of test-enthusiasts, most psychologists of wide experience and scientific caution seem agreed that a modified interview-technique, supplemented if possible by reliable reports and by observation of actual behaviour in standardized situations (e.g., in a playroom with other children, or at 'house-parties'), is still the most satisfactory method for assessing 'personality', and far more trustworthy than any formal tests that have hitherto been devised.

### 9. The Psychology of Training

Education, as the word itself implies, consists essentially in the attempt to develop, deliberately and systematically, the various potentialities of the growing mind. A psychological account of the different methods or techniques available for training the child at school has always formed a large and important part of professional courses for intending teachers; and it was therefore not surprising that, with the introduction of scientific procedures into psychological research, the educational psychologist should set himself to investigate, by experimental or statistical means, the relative efficiency of existing methods of teaching and to devise new and more successful methods.

Experimental psychology, not unnaturally, concentrated first of all on the lowlier and simpler mental processes of sense-perception and movement. This work had a strong influence on classroom practice, especially at the earlier ages and lower mental levels: observation and manual activity began to play a much larger part in the work of the infant departments and of the special schools and classes for the backward or defective. Towards the close of the 19th century, however, an endeavour was made, with considerable success, to apply experimental methods to higher mental processes, such as memory, association, reasoning, and indeed all forms of learning. Much of this work has been done with the needs of the schoolroom definitely in mind; the outcome has been the accumulation of an increasing body of knowledge on such topics as the most economical methods of memorization, the best ways of teaching children the elementary school subjects, the nature, causes, and signs of mental fatigue and mental strain, and the general principles of mental hygiene.

The Child Study Society did much to sponsor experiments in what used to be called 'free discipline' methods—the Montessori method, the Dalton plan, the project method, the play-way, and 'new commonwealths' for young delinquents. As Chief Inspector of London Schools, its most active member, Dr. C. W. Kimmins, was able to encourage and facilitate actual trials in ordinary schools. The Freudian doctrine of the dangers of 'repression', the interest shown by educationists in different schools psychoanalysis, still further fostered this trend towards

freedom, and served to remind the teacher that the child's mind has its emotional and its unconscious aspects as well as the conscious and intellectual.

### 10. Special Disabilities

Considerable research has been undertaken on the training of children suffering from general or specialized disabilities. The devices for teaching the elements of reading and number, not only to infants, but also to the mentally defective, the dull and backward, and those suffering from so-called alexia, have been enormously improved as a result. No disability causes greater concern to teachers in the ordinary elementary schools than backwardness in reading, with its innumerable untoward consequences. Many school medical officers still hold that this may often be due to congenital word-blindness, congenital word-deafness, or a vaguer condition termed "congenital auditory imperception". Occasionally in the special schools or among children of pre-school age, cases are seen in which the implied explanation is highly plausible. In the ordinary elementary schools, however, as careful surveys have shown, genuine instances of this kind are practically non-existent. In the vast majority of cases where this diagnosis has been suggested the child can now be taught to read up to the level of his general intelligence, provided appropriate and up-to-date methods of training are employed.

The earlier work of the child guidance centres was indeed largely concerned with remedial work for children suffering from some form of special intellectual disability. More recently, special courses for teachers of backward classes have been instituted, where the newer psychological techniques can be acquired; and hence an increasing amount of such work can now be carried out in the ordinary classroom, with the occasional supervision of a visiting psychologist.

Not unnaturally, the school medical officer in the past has been tempted to interpret mental disabilities by analogies drawn from physical diseases. In a way that is half metaphorical and half literal, he speaks of delinquency, backwardness or emotional disturbances as 'mental illnesses'. Unless he has had some training in psychology he is not likely to realize how wide and how varied are the quite normal deviations shown by perfectly healthy individuals. One no longer reads medical reports declaring that 60 to 80 per cent of the juvenile delinquents in this area or that institution are feeble-minded. Actually the pathological types of mental deficiency and mental disorder are much more infrequent in children than is commonly supposed. The majority of cases referred to the educational psychologist and diagnosed as psychoneurotic or psychopathic exhibit no more than normal reactions to abnormal conditions. Psychotic and psychoneurotic conditions are undoubtedly found in children of school age. But the former are exceedingly rare before puberty, and the latter are by no means so common as is ordinarily supposed.

### 11. Emotional Disorders

Less success has been attained in dealing with emotional disorders. The psychiatrist, trained in a mental hospital, has in the past tended to interpret these in the light of conceptions acquired in dealing with mental disease in adults,

and promulgated by the particular school of psychological medicine to which he belongs. In this country it has not been easy to secure statistics to show what results are obtained with this or that type of treatment; but the evidence, so far as it goes, shows that the percentages of successes are much the same with all methods of approach. Indeed, what seems to be important is not so much the mode of treatment as the personality of the individual who undertakes it.

There is, however, a growing belief that what is chiefly needed is not so much treatment as training. So far as the child himself is concerned this will consist in a kind of re-conditioning. Undoubtedly the rare pathological cases will require something more, namely, psychiatric investigation and treatment in the narrower sense; but the majority of normal children will respond fairly well to what may be called emotional or moral training. Often this can be undertaken by intelligent parents or teachers, provided the psychologist in charge of the case knows what recommendations to make; in other cases the training has to be undertaken by the psychologist himself.

## 12. The Social Background

Too often, however, the medical approach has consisted in regarding the child as a case to be seen and treated solely in the consulting room or clinic, as though all the causes of his trouble lay within the child himself. To diagnose a case of diphtheria or of endocarditis it is necessary merely

to examine and consider the patient. But with mental conditions it is quite different. The psychologist has always insisted that to study and treat a personality in isolation from its environment—from the psychological 'field' in which his daily life is spent—is like trying to account for the oscillations of a magnetic needle without thinking about the magnetic field. This altered standpoint has an obvious practical corollary. In what are commonly called cases of 'personal maladjustment', the cause of the maladjustment may lie quite as frequently in the child's environment as in the child himself; and, when that is so, what has to be treated and changed is not so much the child as his social surroundings.

All this is now reflected in the fuller attention paid to the psychology of education in training colleges for teachers and in the institution or extension, within the education office, of departments dealing with the social aspects of child welfare. But teachers and social workers cannot cope unaided with every type of case. Hence centres or clinics are urgently needed where the more difficult type of 'problem child' can be dealt with—psychological centres for normal children who need merely individual study and special forms of training, psychiatric clinics for the rarer cases of definitely pathological type. Above all, these centres and clinics should, like the school system itself, be places for research as well as for individual treatment. Only by further research can our knowledge of the growing child and its varying needs be established on a sure and scientific foundation.

## ASSESSMENT OF PERSONALITY

H. J. EYSENCK Ph.D.

*Director, Psychology Department  
Institute of Psychiatry, Maudsley Hospital, London*

- 1 Inventories and questionnaires
  - 2 Objective testing techniques
  - 3 Projective techniques
  - 4 Observational and sociometric methods
  - 5 Summary
- References

Psychologists define personality as "the integrated organization of all the cognitive, affective, conative, and physical characteristics of an individual as it manifests itself in focal distinctness to others" (Warren, 1934). Personality, in other words, is "the sum-total of the actual or potential behaviour-patterns of the organism, as determined by heredity and environment; it originates and develops through the functional interaction of the four main sectors into which these behaviour-patterns are organized: the cognitive sector (intelligence), the conative sector (character), the affective sector (temperament) and the somatic sector (constitution)" (Eysenck, 1947a). The cognitive and the somatic aspects of personality are dealt with in this number in the papers by Vernon<sup>1</sup>, and by Richter<sup>2</sup>.

We shall here be mainly concerned with the temperamental characteristics of the individual and the assessment of his character qualities, being careful to regard character not from the ethical point of view, i.e. as good or bad, but from the psychological, i.e. as strong or weak.

It is clear from these definitions of personality that it is impossible to make an "assessment of personality" as such, just as it is impossible to measure the universe. All we can do is to assess certain distinct traits of personality which are of scientific importance and then proceed to fit these together in order to build up as scientifically adequate a picture of the total person as can be done in the present state of our knowledge.

Assessment of traits has proceeded largely along four separate lines. These are: firstly, by means of inventories, questionnaires, and other pencil-and-paper tests; secondly, by means of objective tests of temperament and character; thirdly, by means of expressive or projective techniques; and fourthly, by means of observational and sociometric methods. These will be discussed in turn.

## 1. Inventories and Questionnaires

Questionnaires originated with the Woodworth Personal Data Sheet at the time of the First World War. Being

interested in measuring the trait of neuroticism in army recruits for the purpose of screening, Woodworth drew up a list of neurotic symptoms. The recruit was then presented with a list of questions such as: "Do you have dizzy turns?"; "Did you ever have a nervous breakdown?"; "Have you ever been off work through sickness a good deal?"; "Do you worry too long over humiliating experiences?", and so forth, and asked to encircle either a "Yes" or a "No" printed at the end of each question according to whether or not he had ever experienced, or was at present suffering from, this particular symptom. His score was the sum total of the symptoms endorsed. (Cf. Woodworth, 1922.)

Much work has since been done on neuroticism inventories of this type, and in certain circumstances they have been found extremely useful as screening instruments (Ellis, 1946; Symonds, 1931). Agreement with outside criteria, such as psychiatrists' ratings, is often quite high (Eysenck, 1947b). This type of inventory has been subjected to much criticism, mainly on the basis that a person can easily falsify his reactions, e.g. deny that he is suffering from a certain symptom in order to appear superior, or claim to be suffering from a symptom in order to "work his ticket", i.e., to obtain his discharge from the army, etc.

These criticisms have led to a rather more empirical method of construction of questionnaires. Starting out with two or more groups which we want to contrast, we ask them a large number of typical inventory questions (over 500 in the case of the Minnesota Multiphasic Personality Inventory Scale (Hathaway & McKinley, 1940; Meehl & Hathaway, 1946), and about 300 in the case of the Humm-Wadsworth Personality Scale (Humm & Wadsworth, 1934)); we then record the percentage of "Yes" answers to each question given by each group of persons, say, neurotics and normals, and then make up a scoring key for this particular trait, which takes into account only those items on which significant differences in responses are observed. Thus, when we find that neurotics differ significantly from normals in their answer to the question, "Do you worry about your health?" we do not conclude that neurotics actually do worry more about their health than normals—which is an inadmissible assumption—we merely say that they tend on the average to assert more frequently than non-neurotics that they worry about their health, and use this difference in frequency of assertion (which is an observed fact) as a basis of our interpretation of questionnaire construction.

This empirical method, since it makes no assumptions of veracity or otherwise, is clearly superior to the older method. It has moreover led to another advance, whereby we try to measure not only neuroticism or other closely similar concepts, but also a number of different personality traits, by the use of suitably contrasted criterion groups. As an example we may take the Humm-Wadsworth Scale, which gives scores for normal, hysteroid, manic cycloid, depressive cycloid, autistic schizoid, paranoid schizoid, and epileptoid types characterized, respectively, by self-control, self-improvement, inhibition, etc. (N); self-preservation, selfishness, crime, etc. (H); elation, excitement, sociability, etc. (M); sadness, retardation, caution, worry, etc. (D); daydreams, shyness, sensitiveness, etc. (A); fixed ideas, restiveness, conceit, etc. (B); ecstasy, meticulousness, inspiration, etc. (E). While far from perfect, this and the

<sup>1</sup> [BMB 1295.—Ed.]  
<sup>2</sup> [BMB 1300.—Ed.]

similar Minnesota Multiphasic Test are a great improvement on the long list of extraversion-introversion tests which were published in great profusion during the past thirty years or so, until it was found that introversion as measured by these tests was really nothing but neuroticism. At present, because of this demonstration, few people use extraversion-introversion questionnaires.

One other important contribution is made by the Humm-Wadsworth and Minnesota Scales. Recognizing that in spite of the empirical construction of the test, cheating is not ruled out, the authors have tried, in a variety of ways, to assess the amount of cheating present in a particular record. This can be done, for instance, by counting the number of times that a person denies the possession of undesirable qualities, on the assumption that no honest person could possibly claim to possess all the good and none of the bad qualities contained in the inventory. In other words, the person claiming too many good qualities is viewed with suspicion.

An alternative method is that of preparing a separate scale, consisting of items which are empirically found to be non-diagnostic with respect to the personality-variables included, but which are somewhat unfavourable to the person answering "Yes"; for example, "Have you ever told any lies in your life?" If too many of these questions are answered with "No", the honesty of the person filling in the questionnaire must be in doubt.

On the whole, it may be said that, when used with care, there is no doubt that questionnaires constructed along these lines, and embodying some of the safeguards mentioned, can give important and valid information about the individual's personality.

Other uses of questionnaires and inventories have been in the fields of attitudes and of interests. A person's attitudes are studied by presenting him with a long list of statements, such as, "Women are intellectually inferior to men", or "The death penalty should be abolished." He responds by agreeing or disagreeing with each statement in turn. This extremely simple method has led to much more complicated measuring devices, attitude scales, and so forth, which are discussed in detail by McNemar (1946), Cantril (1945), Murphy & Likert (1938), and others. Researches on them leave no doubt that attitudes play an important role in personality structure.

Interests are mainly studied from the point of view of occupational interests (Strong, 1943; Kuder, 1939; Lee & Thorpe, 1943), and of values (Allport & Vernon, 1930). Long lists of choices of activities, occupations, types of work, etc., are filled in by the subject and the results scored according to empirically derived keys, by contrasting them with typical response patterns of persons successful in different types of occupations. These inventories have been found very helpful in focusing vocational and other types of interests, and as an aid in vocational guidance when added to an assessment of the subject's abilities.

## 2. Objective Testing Techniques

Objective testing techniques are described in some detail in books by Hunt (1944), Greene (1941), Cattell (1936), Eysenck (1947a), and others. They usually attempt to measure a single trait such as persistence (Howell, 1933), accuracy (Hartmann, 1928), suggestibility (Hull, 1933),

or level of aspiration (Lewin *et al.* 1944; Himmelweit, 1947), by means of objective tests. A large-scale beginning of research in this field was made in the well-known studies of deceit, honesty, and so forth, by Hartshorne & May (1928). These authors devised a large number of tests of anxiety, co-operation, persistence, inhibition, and the like, which they applied to many hundreds of schoolchildren. Examples of some of these are the following.

1. *Double testing technique.* A test is given and the subjects score their own papers by means of a key; later on, they are tested again by means of an equivalent test but without being given a key. Large differences between the scores on these two tests indicate that the subject cheated by copying from the key.

2. *Improbable achievement technique.* The children are given complex tasks, such as tracing a maze with their eyes shut, which are found under control conditions to be extremely difficult or impossible. Success indicates that the subject cheated (e.g. opened his eyes).

3. *Fictitious test technique.* The examinee is given a test, in which some of the questions or items are fictitious. For instance, he may be asked to mark all the books he has read on a long list which includes a large number of non-existent books. Any claim to have read these books is, *ipso facto*, evidence of deceit.

4. *Stealing tests.* The testing situation is arranged in such a way that the subject is given an opportunity to abstract some coins, apparently without any possibility of detection. However, by means of an inconspicuous identification symbol it is possible to find out which subjects have stolen some of the coins.

5. *The vote test.* Children in a class are given a money-prize for some activities in which they have been engaged. They are then asked to vote what to do with the money, which can be used either for certain selected persons in the group, for the group as a whole, for the school of which the group is part, etc. Answers are scored according to the degree of social-mindedness indicated.

6. *The helpfulness test.* An appeal is made to the children for pictures and books to give to children in hospitals. The number of items contributed by each child is his score.

7. *Persistence test.* One measure of persistence is derived from the speed of work of the child when employed for an hour at a monotonous task. Another involves the reading of a story printed in jumbled type, necessitating much effort and attention; the child is allowed to stop at will and is scored on the length of time he kept on with his task. Much evidence is given by the authors of these tests about the reliability and validity of these measures and their inter-relations.

As another example of a rather simple type of objective test we may take the trait of suggestibility, which can be measured objectively in a variety of different ways. In the body-sway test, for instance, the individual is told to stand still with his eyes closed and to listen to a gramophone record which the experimenter is going to play to him. The amount of body sway forward and backward during the initial period is noted; then the record is played, which repeats with slight variations the phrases, "You are falling; you are falling forward; you are falling forward all the time; you are falling forward now," etc., and the effect of the suggestion on the amount of body sway of the subject is

measured in inches. Some people are found to be very suggestible, even to the extent of falling outright, others sway but do not fall, and some are quite immune to the effects of the suggestion. Tests of this kind may be interesting in themselves, or they may be interesting additionally because they serve as measures of something other than themselves. This particular test, for instance, is of interest in its own right, but it is also important because it shows a very high correlation with neuroticism (neurotics tend to be very much more suggestible than normals on it) (Eysenck, 1944); and it also correlates highly with the subject's hypnotizability (suggestible persons are very much more easily hypnotized than others) (Eysenck, 1943).

As one further example of the straightforward test we may mention the "level of aspiration" technique, in which the subject is called upon to perform a task such as, for instance, threading a rather complicated maze. After he has gained some acquaintance with the task he is asked to state how long he thinks it will take him to carry out the task the next time he attempts it. This is called his "aspiration score". He then is given the test and his "performance score" is written down; but before telling him what his performance score actually is, he is asked to say how long he thinks he took over his task. This is called his "judgement score", constituting as it does his judgement of his own previous performance.

Difference between aspiration and actual performance and between judgement and performance are highly instructive, as they indicate the influence of autistic and emotional factors on what otherwise would be a purely rational estimate. It can be shown, for instance, that hysterics tend to have a low level of aspiration; that is to say, for hysterics, the aspiration score is no higher than the actual performance. For normal people, the aspiration score is typically somewhat higher than their actual performance. For neurotics suffering from anxiety states, the aspiration level is typically very much higher than their actual performance. At the other end, the typical anxiety neurotic tends to underrate his performance, his judgement score being much lower than his performance score. A normal person has a judgement score relatively close to his performance score, while the hysteric on the average actually tends to overrate his performance and to think he has done better than he has in fact done. These are some of the ways in which this particular test discriminates between groups who differ considerably in personality make-up.

The tests mentioned so far attempt to measure directly certain personality traits. It has, however, been found that certain types of normal and abnormal people can be differentiated on another basis which derives from purely empirical investigation. The group of tests to be discussed here is similar in many ways to ordinary tests of ability. The difference lies in the fact that we are more interested in differential ability scores as measures of temperament than in the raw ability scores as measures of intelligence. To illustrate, in the normal person we can expect that a vocabulary test will give results very similar to the results obtained from a perceptual intelligence test (we assume, of course, that there are no special defects of education present among the testees). However, when we turn to neurotic groups, we find that among hysterics there is a marked tendency for the perceptual intelligence test to give higher scores than the vocabulary test. On the other

hand, for patients with anxiety states and for depressives the opposite is true; these groups tend to have higher scores for vocabulary tests than for perceptual intelligence tests (Himmelweit, 1945). Similarly, Wechsler (1941), Rapaport, Gill & Schafer (1945) and others have shown that the pattern of scores on the ten sub-tests of the Wechsler Tests of Adult Intelligence tends to form, among psychotics, different patterns for the various psychoses, for patients with brain injuries, as well as for neurotics and normals.

Other differential ability scores of particular interest are those of the Porteus Maze Test when compared with the general intellectual level of the person. It has been shown in several studies that this test measures, in addition to intelligence, a certain quality of foresight, as it is rather obscurely called, which seems to aid its possessor in normal social adjustment. It is a quality which seems to be more closely connected with the frontal lobe than is sheer mental ability, because it has been shown that after prefrontal leucotomy loss of ability on the Porteus Maze Test is much more marked than on any other test of ability. There are other sources of evidence which indicate that the Porteus Maze Test may justly be regarded as a measure of certain non-intellectual, temperamental factors. (See Porteus & Peters, 1947a, 1947b.)

The introduction of objective tests into the measurement of personality is relatively recent and is probably the most promising line of investigation at the moment. Much remains to be discovered, particularly about the interrelations of different tests, but we know enough already to be able to say that a relatively consistent scheme of personality structure can be based on the results of objective personality tests (Eysenck, 1947a).

### 3. Projective Techniques

Projective techniques are based on the theory that an individual betrays his personality in everything he does or says by projecting the contents of his mind on to the material with which he is presented. If, for instance, as in the Rorschach Test (1937), he is presented with a series of unstructured ink-blot which he is asked to interpret, this interpretation will be determined largely by the matrix of his personality. The inverse is also possible; that is to say, by studying his responses to these ink-blot we should be able to argue back to the type of personality which has produced them.

Similarly, in the Thematic Apperception Test (Murray, 1938) the subject is given a number of pictures representing certain rather vaguely constructed situations and is asked to tell a story about these pictures, what is happening, what has led up to the situation depicted, how it will all end, and so forth. The interpretation given to the figures in the picture, the fate which they have endured or towards which they are going, the emotions and feelings which they are made to express, and their attitudes towards each other, are held to be projections of the subject's own feelings, attitudes, emotions, and so on, and are interpreted accordingly.

In the Sentence Completion Test (Rohde, 1947) the beginning of a sentence is presented to the subject, as for instance: "What annoys me most.....", or "I think sex.....", and he has to finish the sentence in some

way himself. The way in which he finishes it is interpreted again in terms of the projective technique.

The Szondi test (1947) has recently become popular on the continent of Europe and in America. It is based on the theory that persons of a certain type will have certain emotional reactions to photographs of people of a similar type, either by way of liking or disliking them intensely. The test, therefore, consists of six series of eight pictures, each picture being chosen to represent one of the eight fundamental types which Szondi recognizes. The eight pictures of each series are spread out before the subject and he is asked to select the two he likes best and the two he likes least. A record is made of his choice and the same procedure is repeated for the remaining five series. From the pattern of his choice a detailed personality diagnosis is made. This test is introduced by its author in conjunction with a rather pretentious, semi-metaphysical and pseudo-genetic scheme of personality theory which is demonstrably false. However, this does not necessarily prove that the test itself is valueless and there is much subjective testimony in its favour.

While some projective techniques, such as the Szondi Test and the Thematic Apperception Test, are relatively novel, others are relatively old, as far as psychological testing techniques go. Among these are Freudian dream-interpretation, the study of paintings and artistic productions generally, and play techniques, in which the child's or adult's methods of play are interpreted in accordance with the projective hypothesis.

Probably, the earliest projective technique was the word association test, first used by Galton, in which the experimenter says a word to the subject, who has to respond with the first words that come to his mind, the theory being that his response will reveal certain associative links of which he himself may be unaware. This technique has been elaborated a good deal by combining it with others, such as, for instance, a recording of changes in the electric resistance of the skin (the psychogalvanic reflex or electrodermal response), motor movements on the part of the subject (the Luria reaction), and so forth. The Luria technique, which consists essentially in the study of the disruption of motor responses caused by emotional experiences, leads, naturally, to another type of projective test, namely, that concerned with the study of expressive movements (cf. Luria, 1932). Here, we have a large body of speculation and experimental validation which has arisen out of the study of handwriting (graphology), and also of the more strictly controlled measures of a person's ways of moving his hands, feet, or whole body (Allport & Vernon, 1933), which can be interpreted as expressive of his personality.

On the whole, it cannot be said that these techniques have fulfilled their early promise. Interpretation is still very largely subjective, intuitive, and unscientific. Evidence concerning the reliability of these methods is disappointing and evidence concerning their validity is almost wholly lacking or of such a kind as not to be particularly convincing. Nevertheless, attempts have been made recently to make the scoring of these tests more objective and to elude proper evidence in their favour; should these attempts prove successful, there is little doubt that projective techniques would assume a very important position indeed in the armamentarium of the psychologist.

#### 4. Observational and Sociometric Methods

Among the earliest methods of personality assessment were those of simple observation and rating, a group of methods which, presumably, should include the interview also. Much work has been done in recent years to refine and objectify these methods, as may be seen, for instance, from the account given by Vernon (1938), Symonds (1931), Greene (1941), and others. Outstanding examples of careful observational records are Bühler's (Bühler *et al.* 1939) twenty-four-hour records of family situations, collected by trained workers who went into private homes, and Newcomb's (1929) analysis of detailed daily records made by counsellors in a summer camp in order to assess extraversion and introversion.

A particular variety of the general method of observation is that of time sampling. The subjects under investigation are observed for a specified number of minutes, a certain number of times every day. A record is made of the frequency with which they indulge in certain types of activity such as laughing, crying, quarrelling, etc., and this record forms the basis of the study. Such reports can be made very objective and are usually extremely reliable (Olson & Cunningham, 1934). They are particularly useful in a social situation where the experimenter has little control over the variables in which he is interested.

As an additional aid in the analysis of personality traits in social situations, the investigator nowadays often makes use of sociometric techniques (Moreno, 1934). These consist essentially in asking each member of a group with which other member of the group he would most like to participate in certain activities, which member he would like to sit beside him at meals, etc. From these records of attractions and repulsions between members of the group a pattern is derived which has been found to be very useful in many ways.

This method is particularly relevant to the part of the definition of personality quoted at the beginning which stresses the way that a person's "cognitive, affective, conative, and physical characteristics manifest themselves in focal distinctness to others." The sociometric technique shows us through the eyes of "others" just how the individual's personality manifests itself and techniques of this sort are therefore indispensable adjuncts in a thorough study of personality. During the recent war, modifications of these ratings and sociometric techniques have been found of some use in officer selection procedures.

#### 5. Summary

We have been able to give only a small number of examples to illustrate the main types of personality tests used nowadays. The interested reader will find a complete review of the hundreds of tests in common use in the *Mental measurements yearbook* (Buros, 1949), in the bibliography by Hildreth (1945) and in other similar compendia. The setting in which these tests ought to be evaluated is probably best given by Stagner (1947) and at greater length by Gardner Murphy (1947) or by Allport (1938). Greater details about the methods of measurement, and evidence regarding the reliability and validity of tests, as well as their use in various connexions, may be found in books by Hunt (1944), Greene (1941), Cattell (1946) and Eysenck (1947a).

While the assessment of personality, judged from the

points of view of validity and reliability, is still very far from the certainty which inheres in measurement as understood by the physical sciences, there can be little doubt that the methods reviewed here have led us a long way

from the subjectivity of pure intuitive understanding and have enabled us to come to grips, on a purely objective basis, with this very protean and elusive thing—the human personality.

### 1. General Intelligence Tests

#### a. Tests for Children

The revision by Terman & Merrill of the Stanford-Binet scale was published in 1937, and has by now become the standard test for measuring the intelligence of individual children in schools and clinics. It is a reliable and objective instrument when properly applied by trained testers, and it covers the whole range of mental ages from 2 to about 23 years (superior adult level). But it shows certain defects, particularly at upper ages. Evidence is accumulating that the order of difficulty of the component sub-tests, and the standardization, are inaccurate in Britain. Mental ages above about 12 years seem to be seriously exaggerated, so that high intelligence quotients (I.Q.'s) are much too high. The heterogeneous content of the scale is also open to criticism. True, this helps to maintain the child's interest, and allows the tester to observe the child's mind working in a great many different ways; but it also tempts the tester to jump to unwarranted conclusions about special abilities and disabilities. The verbal, practical, spatial, numerical, reasoning, and other types of sub-tests do not provide adequate measures of distinctive 'types' of ability. At the same time the scale does not measure one and the same ability throughout. Investigations using the technique of factor analysis, by Burt (1939) and others, show that it is primarily a measure of *g*—the general intellectual factor—but that it is biased or distorted in various directions at various age levels. The verbal-educational or *v* factor does enter to a considerable extent, particularly at higher mental ages (hence educationally retarded children tend to be handicapped), and numerical, spatial, and other abilities exert minor influences.

\* This article is published with the approval of the Lords Commissioners of the Admiralty, but the responsibility for any statements of fact or opinions expressed rests solely with the author.

#### b. Tests for Adults

For these and other reasons a different individual test is generally preferred for testing adolescents and adults, namely the Wechsler-Bellevue scale (Wechsler, 1939). The full scale consists of six verbal and five non-verbal (performance) sub-tests. Each sub-test contains numerous graded items and yields a separate score. From the total scores a verbal and non-verbal I.Q. are obtained, and separate norms are provided for different age groups. Unlike the Terman-Merrill scale, therefore, the Wechsler scale is homogeneous; it measures the same combination of abilities at all levels. It is somewhat lengthy to apply, and several abbreviated versions have been adopted. In the Royal Navy and the Army during the war, for example, individual testing was frequently carried out with the comprehension, similarities and vocabulary sub-tests from the Wechsler, and with the Trist-Misselbrook revision of Kohs Block Design as a performance test.

#### c. Group Tests

Experience in the Services suggests that, except perhaps among defectives and psychiatric cases, the intelligence of adolescents and adults can be measured as effectively by a battery of suitable group tests as by any individual scale. Such a battery usually includes a non-verbal test such as the Raven Progressive Matrices, one or two verbal and arithmetical tests, a mechanical test and a spatial judgement test. Follow-up research has proved that this gives useful predictions of capacity for almost any Service job. The particular tests found most valuable in naval, military and air-force personnel selection have been described by Vernon & Parry (1949). The results of these tests are usually expressed, not as I.Q.'s, but as Selection Groups or Grades. SG 1 (or A) represents the top 10 % of scores, SG 2 (or B) the next 20 %, SG 3 (or C) the middle 40 %, SG 4 (or D) the next 20 %, and SG 5 (or E) the bottom 10 %.

Few group tests of note for children have been published in Britain during the past 10 years or so. Nevertheless the practice of including an intelligence test, such as one of the Moray House series, in examinations for secondary school allocation at 11 or 12 years has become more and more widespread. When tests are thus employed competitively, serious problems of coaching and of the effects of practice arise. Previous practice on similar tests will raise intelligence quotients by an average of 2 to 10 points, depending on the particular type of test. Research suggests, however, that the law of 'diminishing returns' operates, hence coached children have relatively little advantage over uncoached if all are given some practice at the time of the crucial test.

For testing children of 3 to 5 years, the Terman-Merrill and the Merrill-Palmer scales still seem to hold the field in Britain. It is generally admitted that no tests for even younger children (such as the Gesell schedules) provide reliable indications of later intelligence. There has been little change also, during the past decade, in performance tests of intelligence, except in their price; the cost of the better known scales (Pintner-Paterson, Arthur, Collins-Drever, Alexander) and of the common picture and form-board tests has become almost prohibitive. That testers should be forced to pirate tests or to use non-standard materials is a most unsatisfactory state of affairs. Actually

it is highly probable that just the same ability or abilities could be measured by printed pictures and diagrams as by practical tests, but manipulative materials naturally arouse more interest among young children and dull adults and so produce easier rapport. Most picture and formboard tests are rather poor measures of the *g* factor, while constructional tests and paper and pencil tests involving imaginative manipulation of shapes bring in, in addition, the spatial judgement or *k* factor.

## 2. Diagnostic Testing and Factor Analysis

Mental testing has become much more detailed or analytic during the past decade. Important developments have occurred along two main lines which, though largely independent so far, should eventually complement one another. In the nineteen-twenties and early thirties testers were for the most part content to measure general intelligence by means of batteries of miscellaneous items or sub-tests, together with a few more specialized abilities such as mechanical, arithmetical, musical, etc. Psychologists in clinics often guessed that particular types of items were diagnostic of particular mental functions but they seldom possessed any empirical evidence for these "hunches". The two methods by which such evidence is now being accumulated may be termed the clinical and the factorial.

### *a. Clinical Methods*

The clinical approach involves establishing differential test performances among different clinical groups. Using the Wechsler-Bellevue scale, for example, Rapaport, Gill & Schafer (1945, 1946) and others have described different patterns or profiles of scores on the various sub-tests among schizophrenic, paranoid, depressive, hysteric and other psychotic and neurotic patients. The greatest amount of work has been done on tests of mental deterioration. It is widely agreed that intellectual ability can be divided into what Cattell (1943) calls "crystallized ability" or the reactivation of past experiences and knowledge, on the one hand, and "fluid ability" or the present efficiency of mental functioning, on the other hand. The former is usually measured by vocabulary tests, or sometimes by information and arithmetic tests, which are relatively little affected by pathological conditions, the latter by tests involving abstraction or seeing new relationships or by tests of quickness of response. The Wechsler sub-tests provide contrasting scores of these two types. Probably less reliable, but widely employed, is the Shipley-Hartford deterioration scale, based on two short group tests of vocabulary and abstraction. Babcock's mental efficiency test (Babcock & Levy, 1940) uses, in contrast, three tests of learning (e.g. recall of stories), three motor tests (speed of writing, etc.), and three of repetition (digits forward and backward). Brody (1944) provides a useful review of these and other tests, and points out the difficulties of distinguishing actual deterioration from the effects of age and of the lack of co-operation so common in mental patients.

Innumerable other tests have been devised to measure conceptualization and generalization, perceptual and learning capacities, and other mental functions which are supposedly affected in cases of cerebral injury, aphasia and psychosis. Similar tests are used for exploring the effects of shock therapies, drugs, leucotomy and lobotomy; they include

the Hanfmann-Kasanin concept-formation test, Weigl's and Vigotsky's sorting tests, Bender's visual gestalt test, Rorschach inkblots and other projection tests. Descriptions may be found in Rapaport *et al.* (1945, 1946) and Klebanoff (1945). Many of these are still in the qualitative stage, and few quantitative differences between different types of mental patient have yet been firmly established. Without denying the fruitfulness of investigations with such tests, we should also realize that most of them do not measure adequately defined and distinctive abilities. For example, a study was made of 15 alleged tests of 'memory', which showed that the underlying ability measured by them was nothing more than *g* (Eysenck & Halstead, 1945). It is desirable therefore that diagnostic testing should be carried out only by persons who possess both clinical experience and a good grounding in psychometrics, which will help them to avoid the fallacies of faculty psychology and of over-reliance on intuition. The days are past when psychologists in mental hospitals were merely asked to "I.Q." a patient, but their diagnostic tools have certainly not reached the same scientific precision as those of, say, the biochemist.

### *b. Factorial Methods*

The alternative approach of factor analysis attempts to map out the distinguishable factors or types of ability by studying the extent of overlapping (correlation) between large numbers of tests. The dependence of each test on such factors can then be determined (its 'factor saturations') and we can choose one or more tests to measure precisely the abilities in which we are interested. Spearman's views (1927) on the all-pervasiveness of the general ability or *g* factor are largely confirmed by recent research, but numerous additional types or sub-types have been isolated. We have already mentioned the verbal, numerical, spatial and mechanical. Thurstone & Thurstone (1941) have described seven primary factors which are remarkably similar at all age levels from 6 years to adulthood, namely word fluency, number, space, rote memory, perceptual speed, and inductive and deductive reasoning. There is still however considerable disagreement as to the number and scope of the factors required to give a complete map of human abilities. It is reasonable to suppose that children and adults suited to different types of education and to different jobs will have different profiles of scores on such factors, though research in this direction is only just beginning. Several batteries of 'differential aptitude tests', designed to yield profiles, have been published in the USA by the Thurstones (1941), the United States Employment Service (Dvorak, 1947), and others. But their construction and standardization are so complex, time-consuming and expensive that nothing comparable is yet available in Britain. It is noteworthy that many American group-tests are issued with special answer sheets which can be automatically scored by an electrical counting machine.

## 3. Vocational and Educational Tests

In the field of vocational selection and guidance, there is less emphasis nowadays than formerly on analytic or analogous tests—that is, tests aimed at the specific aptitudes supposed to underlie each job; the tendency is rather to measure the more general abilities which enter into a wide

variety of jobs. In the British Forces during the war this policy was dictated largely by shortages of materials and of persons experienced in job analysis and test construction. But several investigations of tests for gunners, motor drivers and other categories indicated that specialized tests add so little to predictions based on general tests plus background information (obtained by questionnaires and interviews), that it would be uneconomic to introduce them (cf. Vernon & Parry, 1949). Similarly Guilford (1948), from experience in the United States Army Air Force, points out that tests designed to measure the abilities considered to be involved in a particular job often correlate more highly with success in other jobs, and he prefers tests whose factorial content is known to those based on subjective analyses of job requirements.

Two types of vocational tests were, however, found specially useful as supplements to a general battery, firstly, tests of information and secondly, 'work-sample' and 'miniature situation' tests. In the Services a simple test of everyday mechanical and electrical knowledge gave better indications of trainability in mechanical and electrical jobs than did practical tests involving the assembly of mechanisms. Similarly, tests of trade knowledge yielded reliable assessments of relevant experience among tradesmen. Work-sample testing involves trying out the candidates for a short time on the job itself. Thus the wastage of pilots in the RAF was spectacularly reduced by eliminating trainees who made least progress in the first 5½ to 11½ hours of flying instruction. Some evidence was obtained that the same approach would be the most hopeful one for selecting gunnery ratings in the Navy. Often, however, the trials can be carried out, as it were, in miniature. Aptitude for learning the Morse code among potential signallers and telegraphists was measured by training recruits for some 20 minutes on three actual Morse characters, and then testing the speed and accuracy with which they could receive a long series of these three characters. Under this heading also fall the important developments of recent years in methods of selecting officers, business managers and high-grade civil servants, in which observations are made of the personal and social reactions of small groups of candidates engaged on exercises psychologically similar to their future jobs. These methods cannot, however, strictly be called tests, since they do not involve objective measurements of the candidates' behaviour. Depending as they do on subjective assessments, their value varies tremendously with

the acumen and experience of the observer or testing officer.

Tests of educational attainments are particularly important in examining children at Child Guidance Clinics, and in educational selection. For the former purpose Burt's series of (mainly individual) tests is still invaluable, though standards have tended to rise since they were published in 1921, and then to drop markedly since 1939. Much as in the field of intelligence, testing in this field also is becoming more analytic. For example, Schonell's (1942) diagnostic reading and arithmetic tests assist the clinic psychologist to plan the most appropriate remedial coaching for each backward child. An outstanding investigation of the relative value of intelligence and educational tests, school examinations and teachers' opinions, for selection at 11-12 years, has been published by McClelland (1942). There is at present considerable interest in, but also disagreement as to, the possibilities of differentiating the technical from the academic or other types of pupil at so early an age, by such tests as Earle's Duplex series and Alexander's performance scale. That tests can play a useful part in the selection of university students is shown by Eysenck's (1947) review. Promising attempts have also been made in America to test aptitude for professional training—medical, legal, engineering, etc., and experiments with tests for medical students are under way in Great Britain.

#### 4. Conclusions

The main themes of our survey are the great expansion in the scope of mental testing in recent years, and the search for scientific evidence as to what our tests actually measure. We should not conclude, however, without some words of caution. The development of larger numbers of more accurate tests enhances the need for psychologists experienced in construction, application, and interpretation of results. Adequately trained testers are in very short supply, and there are grave dangers in the over-popularization of testing among amateurs.

Finally the role of tests should not be exaggerated. War-time research has indeed proved the superiority of scientific methods of assessing abilities over older methods, such as the uncontrolled interview and the essay examination, which depend too much on the vagaries of human judgement, but it has also shown how far tests are at present from covering all the factors that make for educational or vocational success or failure.

In this paper I shall attempt to outline the main features in the science of analytical psychology which may be of interest or use to the psychotherapist in the practice of his art. In so doing I shall refrain from describing psychotherapy in detail and this for several reasons: firstly, it would not be possible within the scope of this article; and secondly, even if it were, there are too many psychotherapeutic methods and processes to make a comprehensive description possible at the present juncture. Neither of these reasons, however, touches the central core of the problem, which lies in the fact that psychotherapy, in a deeper sense, is individual in its nature. (Group psychotherapy is not included in these notes.) Because of this, attempts to classify psychotherapeutic methods can have only relative value and will never eliminate the fact that the process is a dialectic developing between two unique persons who, because of their individuality, are not subject to classification.

In this article the individual element in psychotherapy will be taken as an essential part of the process. Attempts to eliminate it are merely retrograde, since they bring us to a state characteristic not of civilized but of primitive peoples who, owing to their undeveloped consciousness, regard individuality as a dangerous phenomenon; indeed it requires such an effort of mind on their part to discriminate between one person and another that they find it almost beyond their capacity (Jung, 1934). Since any psychotherapy worthy of the title has become identified with the development of conscious discrimination, we cannot regard uniformity of method as an aim, for this necessarily implies that patients are uniform and have no individuality. To apply a method is, however, the correct procedure in cases where the problem is one of adaptation in the social sense, that is,

where the patient is too individualistic and remote from the instinctual basis of his life. However, the method will fail if it violates real individual values.

Methods are tools in the hands of the doctor, and the way he, as a human being, uses them is the significant factor in psychotherapy; in short, his personality can never be overlooked but is rather a central factor in the therapy. Because of this consideration, analytical psychology has always placed a personal analysis in the centre of its requirements for the training of its analysts. This analysis aims not only at raising consciousness to a level which can reasonably be expected of the candidate, but also goes far to ensure that his desire to become an analyst is founded upon a secure basis. This occupational test is necessary because there are too many who aspire to cure others because of their own inability to cure themselves. In such cases, if the training analysis of the candidate is successful, the desire to become an analyst will simply disappear.

But once the analysis is completed the analyst cannot sit back and assume that he is now without blemish. Therefore the analytical psychologist sits facing, or beside, his patient; the couch is seldom used though some analysts consider it valuable for patients who cannot relax in a chair. Sitting in view of the patient ensures that observations can be made by eye as well as by ear. The position of sitting in full view also expresses the analyst's willingness to treat the subject as an equal on a fundamental plane, even though the analysand may not believe this to be so because of the transference. Lastly, the position shows the analyst's willingness to reveal himself. This last requirement is the one above all which makes it essential for the analyst to be aware of himself, and sufficiently integrated to be capable of knowing and tolerating his own unintegrated condition. On the face of it, unintegrated responses look undesirable, but inferior reactions are not to be avoided and, so long as they are recognized as such, can be of positive as well as of negative value. On the other hand, concealed inferiorities fascinate and hinder the analytical development just because they cannot be seen but only vaguely felt as unexplained consequences of the hidden complex within the analyst.

### 1. Main Concepts of Analytical Psychology

Before going on to consider further aspects of the analytical procedure, it will be necessary to consider briefly the fundamental ideas upon which the practice is based. The best known work of Jung (1933), upon which analytical psychology bases its practice and research, consists of two interlocking structures—on the one hand, the theory of types concerned with different kinds of consciousness; on the other, the theory of the unconscious which Jung divided into two parts—a more superficial, personal layer and a deeper, collective or impersonal layer.

#### a. *The Theory of Psychological Types—the Psychology of the Conscious Mind*

This theory is an elaborate structure, by no means easy to understand and apply, but it provides the psychotherapist with a means of determining the attitude of the conscious mind. It is therefore a stepping-stone towards differentiation, somewhat like psychiatric classifications, but aiming to assess, via the attitude of the conscious mind, the personality as a whole rather than its pathological part.

According to the theory, there are four possible attitudes of consciousness: two rational, *thinking* and *feeling* (valuation), and two irrational, *sensation* and *intuition*. To this already complicated structure is added the notion that the conscious attitude may be directed outwards, *extraverted*, or inwards, *introverted*.

Once the attitude of the conscious mind has been determined, we are in a position to infer the attitude of the unconscious, because of its opposite attitude to that of the conscious mind. The unconscious attitude complements that of consciousness and contains the neglected, undeveloped and incompatible functions.

A moment's reflection will show that the number of "types" which this system will contain is large. Partly for this reason and partly because we know that considerable modification in type is possible, it could never be used in a rigid fashion. The eight types which Jung describes in his classical work make up an axial system through which one may orientate oneself amongst the variety of human beings whom the psychotherapist is bound to meet in his practice. Here we may note that the whole system is bound up with the process of individuation and the fourfold structure of the psyche of which the type theory is an expression.

#### *b. The Unconscious*

Jung divided the unconscious into two layers which he called the acquired, repressed or personal unconscious; and the innate, collective or impersonal unconscious—the fundamental matrix out of which consciousness grows.

The theory of the collective unconscious is based upon the notion that the fundamental structure of the psyche is uniform and that in the last resort, if we could eliminate consciousness, there would be little or no difference between one human being and another. There is therefore an "X", psychic but unconscious in its nature, out of which consciousness grows. This "X" is the precursor of fantasy. When it appears in fantasy form, it is in the first place the symbolical expression of instinct; but it always adds something else which is not, and never has been, exactly defined, and which is, and always has been, referred to in such terms as "spirit", "pneuma" or "numinosum"—terms which defy intellectual appraisal. Jung's idea is then that the unconscious is a fundamental reality and he uses St. Augustine's term "archetype" to denote its functional parts. The essential nature of the archetype is indefinable, in very much the same way as the mathematical symbol  $\pi$  is indefinable, that is, however far you go there is no possibility of determining exactly what it is. For this reason, the archetypes are understood as fundamentally unconscious functions.

It is evident that a fantasy is a more or less conscious product and its content is often, but not always, referable to various already known images. In consequence, the archetype usually shows itself by its selective capacity and is consequently more or less obscured. We can, however, remove these darkening components by the method of amplification, in which parallel myths are brought forward to amplify or show up the essential core within the conscious form. This method of amplification is therefore held by analytical psychologists to be an essential acquisition of the analyst. It necessitates a considerable knowledge of mythology and comparative religion, which must be accumulated, not with the object of burdening the analyst unnecessarily with intellectual knowledge, but so as to

provide him with the necessary means to orientate himself and, if necessary, his patient as well. This means that any analyst's training involves the acquisition of considerable knowledge concerning the growth of civilization in its many aspects.

#### 2. The Pattern of Analysis

The pattern of analysis can be laid down as a process consisting of three stages.

The first consists in confession of material already conscious, proceeding to clarification of subliminal material which has been half- or pre-conscious.

When this material has been discussed and interpreted we can proceed to the second stage, the analysis of the personal unconscious. This consists in unearthing memories and past experiences which have not been resolved, and in the clarification of personal feelings which, through the action of repression, have not been allowed to come into consciousness.

As this process goes on we begin to see the archetypes of the collective unconscious emerging, at first hidden behind the personal experience and then coming more and more into the open; this indicates the onset of the third stage. The classical analysis develops now as an internal dialectic which releases the patient more and more from the analyst owing to the operation of the individuation process. It is this process, first described by Jung (1928), which culminates in the emergence of the *self* after a more or less typical development in which the archetypal figures come increasingly to the fore in various shapes, called "The Shadow", the "Animus" and "Anima", the "Old Wise Man" and the "Old Wise Woman".

We can view this typical analytical process as part of the whole development of an individual life, which gradually unfolds itself as the years go on. We can indeed link it up with the phases of life, for the age of the patient is of essential significance as a guide to the conduct of psychotherapy. Jung described the individuation process as a phenomenon of the second half of life, i.e. starting between 35 and 40 years of age. At this stage the ego is firmly established and the individual is able to give libido to the more fundamental problems of the living process in a more impersonal form. During the first half of life, on the contrary, the problem centres first of all round the development of the ego in connexion with personal relationships, as a preparation for more independent living. For this purpose the parents are necessary containers of the child's existence. When the child becomes a man or woman, the problem changes, and becomes then how to achieve sufficient independence of the parents, to work, earn a living, marry and found a family. When this is done, what next? A peak has been reached, after which a gradual descent to old age and death begins—it is a period of increasing introversion. At this peak, a change occurs which heralds the increasing need for revision and reflection upon the fundamental problems of life as experienced by the individual; in other words, the problem of individuation comes to the fore. If we consider the therapeutic problems in the light of these observations we arrive at the conclusion that different periods in life demand different kinds of attitude. In the first half, the problems are of a personal nature, and in consequence the therapeutic process will centre round

the personal unconscious ; in the second half, the collective unconscious will contain the essential problem of individuation. Our scheme will therefore serve as a guide to be taken in conjunction with the stage in life through which the individual is passing.

### 3. Frequency of Interviews

Analysts vary in their opinions regarding the frequency of interviews ; moreover, the stage reached in the analysis has to be taken into consideration. Jung (1935) regards four times a week as sufficient. In the early stages of analysis frequent interviews are desirable, particularly during the period when the contents of consciousness are being confessed and when the personal unconscious is being analyzed. During this period the transference is developing and is being handled on the objective plane. By this is meant, objective situations in the past are being revealed through the transference which has to be analyzed in detail in relation to the past.

When, however, the analysis reaches the level of the collective unconscious a different situation begins to arise. The contents of the analytical transference become less and less personal and, provided the ego is sufficiently established, the subject is able to take responsibility for the material arising out of the unconscious, which he sees more as an inner problem of his own. This process can be fostered by interpretations which bring the patient into relation with himself—interpretations on the so-called subjective plane. These interpretations herald the synthetic part of the analysis.

With these considerations in mind, it follows that the number of interviews may be reduced at this juncture. It is part of the natural development towards taking responsibility, i.e. psychosynthesis.

As a consequence of these reflections, and taking them into consideration with the section on the pattern of analysis, we can see that interviews will be more frequent for subjects under 35-40 years of age than for those who are older. This is so because in the first half of life the problems are predominantly personal, whilst in the second, they become collective and impersonal.

### 4. Dream Analysis and Active Imagination

Analytical psychology distinguishes two ways of approaching dreams. The first consists in employing free association to the dream material. By this means is produced a long string of seemingly disconnected material which leads to the complexes. The other method consists in determining the dream context. This is done by amplification ; according to this method we need only association material in order to show the context. Two kinds of contexts are required—the personal context, in which case the patient's associations will provide what is necessary, and the collective context, in which case mythological material may be supplied by the analyst in order to throw into relief the collective matrix out of which the dream symbol arises.

Though the use of free association has become familiar, amplification has not, and it will therefore not be out of place to say something further about its nature. Amplification is an extension of a natural process which has been observed in dream series. In these series, the symbolism develops in a particular way, and refers to a central problem

or symbol by means of analogies, revolving round it and gradually concentrating more and more upon its central nature. Thus the material referring to the central symbol amplifies the central content or throws now one, now another, of its aspects into relief until an almost complete picture is built up. By bringing parallel myths to bear upon a symbolical product we intend the same thing, and are therefore employing the "method" of the unconscious, but concentrating into a short space what may take months or years to develop.

These methods are preliminary ; they precede the interpretation, which cannot be made without collecting the necessary material. When this material has been collected the question arises of whether it needs to be understood upon the objective or the subjective plane. The objective plane refers to external objects, i.e. actual people in the environment ; the subjective, to internal "persons" or archetypes. Which interpretation is relevant depends upon the attitude of the conscious mind, whether it be extraverted or introverted, and the stage of analysis which has been reached.

Without going further into the complications of this problem, we shall follow up the consequences of subjective interpretations which lead inwards to the collective unconscious. When the interpretations bring the archetypes into clear relief, the process of active imagination can be set in motion. In this process the conscious mind is brought into relation with the archetypes which, out of their own activity, produce fantasy images ; an inner drama starts, in which the conscious mind participates in a more or less active way. This process is analogous to artistic creation or religious inspiration, showing analogies with such processes as meditation and contemplation.

The process, when in action, needs to be undertaken under analytical supervision within the transference, at least in the first place, though as the development proceeds and becomes more and more real the transference, now consisting of collective archetypal contents, gradually gets undermined until the individuality eventually emerges as a central core round which the personality revolves as a coherent whole.

Active imagination does not do this ; it is simply a valuable adjunct to a development which can as well occur in dreams. This development is augmented and hastened forward, however, by allowing the material to emerge in the day-time as well as at night.

### 5. Conclusion

This brief review of the contribution of analytical psychology to psychotherapy can do no more than hint at the processes which have been described. The scientific work undertaken has complicated the psychotherapeutic field, but this complexity was certainly there in the first place. In approaching the psyche and describing its phenomena, analytical psychology claims to have placed the psychotherapist in a position to deal more effectively with the obscure realms with which all those engaged in that art have to contend.

The question will necessarily be raised : in what kind of cases will Jung's methods be most useful ? From what has been said, it will be clear that Jung's work frees us from the necessity of pursuing one method alone, but rather provides

The reader who turns expectantly to reviews of "recent work" on psychology hoping to find therein evidence of outstanding "progress" during the past ten years is doomed to some disappointment. In the case of the physical sciences, once the fundamental principles governing any particular branch have been laid down, one may expect to find that year by year extensive advances have been made in a number of directions. It is quite otherwise with psychological science. The more dynamic it is and the more it is concerned with the unconscious functions of mind, the more it works against a head of resistance and consequently the slower the pace of discovery. Even the impact of war, which, again in the case of physical sciences, usually accelerates the rate of discovery, produces little or no positive effect in the psychological field—rather the contrary. The tendency of psychology during war and for some time afterwards is reactionary. The energies of psychotherapists are diverted to the application of short-cut forms of treatment, usually old methods dressed up as new. Hence no discoveries of consequence are made.

With this preamble, it can be stated that since the death of Freud in 1939 no advances of importance have been made in the field of psychoanalysis in Great Britain.

\* [See also article by W. Clifford M. Scott in this number (BMB 1293).—Ed.]

Nevertheless certain significant changes in the tendency and direction of the psychoanalytic movement have taken place. And these are worth recording.

### 1. Development of Psychoanalysis in Britain

Before doing so it is desirable to outline briefly the development of the psychoanalytic movement in this country. It commenced only a few years before the outbreak of the First World War. At that time Freud's theory of the unconscious, of dreams, and of the neuroses was well established; and a small group of pioneers centred in London, having founded the London Psycho-Analytical Society, devoted themselves to practising and teaching Freudian principles. After the close of the war this society was reconstituted as the British Psycho-Analytical Society. In the meantime Freud had developed and expanded his theories in a number of directions and was about to enter the second great phase of his theoretical formulations. Up to that time the concept of unconscious mental conflict, and with it the theory of neurosis, had presumed an antithesis of libidinal (in the general sense, sexual) instincts and the ego-instincts, in particular the impulses of self-preservation, together with certain reactive (aggressive) impulses. The neuroses were regarded as compromise formations representing both the repressed and the repressing forces, which latter were held to operate through the unconscious ego and to be activated by the ego-instincts.

The new orientation in Freud's theory was due to a number of factors. Most important of these were the extension of his researches into the structure of the unconscious ego, and fresh understanding of the part played by the impulses of aggression in ego development. The groundwork had already been prepared by his investigation of melancholia, from which Freud was able to postulate the existence of early differentiations of the unconscious ego. The modern psychoanalytical concept of the super-ego, or unconscious conscience, was developed from these studies. The function of the super-ego, which is derived essentially from an internalization of parental influences, is to exercise, or more accurately to instigate the unconscious ego to exercise, control over primitive impulses threatening danger to its stability. At the same time Freud was able to demonstrate that the forces giving rise to disorder of super-ego function, of which melancholia is the exquisite example, were not only the narcissistic components of the libido with which the ego is invested, but the aggressive

## ANALYTICAL PSYCHOLOGY

*Continued from page 26*

us with a number of pointers which will guide the psychotherapist in his relationship to his patient. Therefore this work is applicable to a wide variety of patients, but the special contribution of Jung's work is to introverted psychology and to those in the second half of life. We may say, therefore, that the introvert will naturally be more attracted than the extravert, whilst older and more mature personalities, who need to evaluate their lives in terms of original experiment and through this to find an

individual rather than a collective solution, are likely to find in analytical psychology a means of arriving at an answer to their problems.

Finally, we should not end without referring to the special contribution which analytical psychology has made to psychiatry. It has proved especially useful in cases of schizoid personality and thus provides a means of approach to schizophrenia itself.

impulses which are loosened when any pathological disturbance takes place in the relation of the ego to its instinctual objects. These aggressive impulses, when let loose within the unconscious ego, give rise to a variety of pathological changes varying in accordance with its stability from mild neuroses to the most extensive psychoses.

Obviously a new orientation in the Freudian theory was necessary: and Freud did not hesitate to make the necessary changes. Abandoning his concept of special (non-libidinal) ego-instincts, he postulated the existence of an unorganized psychic institution, the id, which is also a reservoir of all instinctual forces. He also distinguished at the periphery of this system ego-institutions, i.e., the super-ego, concerned with the supervision of libido and aggressive instincts, and the ego proper, concerned with the maintenance of adequate systems of discharge in reality. The self-preservative impulses were then regarded as libidinal in nature—an extension therefore of the earlier and more limited concept of narcissistic libido; and the instinctual antithesis between libido and ego-instincts was replaced by a deeper antithesis between the “erotic” or “life instincts” and the aggressive instincts which Freud held to be a derivative of a fundamental “death-instinct” or “innate tendency” of living matter to return to the inanimate state. These views he set forth in three monographs (Freud, 1922a, 1922b, 1927).

The impact of these new ideas on the British Psycho-Analytical Society may be said to have taken effect roughly about 1926. Up to that time the Society was, on the whole, a conventional group undisturbed by schisms and controversies and, perhaps for that very reason, rather uninspired. The bulk of psychoanalytical research and discovery was the work of three groups, in Vienna, in Berlin and in Budapest, although it is undeniable that up to a few years before his death Freud himself was responsible for the lion's share of this work. In England, apart from the papers of Ernest Jones (cf. Jones, 1948), little of significance was published. Naturally, therefore, the new ideas were at first taken over without reservation, although a few members found difficulty in accepting Freud's concept of the “death-instinct”. As, however, the fundamental discoveries regarding conflict, repression, symptom- and dream-formation and the nature of transference were not disturbed by this theoretical concept, there was at first no sign of scientific differences within the British group.

## 2. Impact of the European Groups

That changes soon took place was due to a number of factors. In the first place psychoanalysis, like all other sciences, is to some extent subject to the influence of fashion. It soon became the custom to see unconscious aggression in every analytic manifestation, and to speculate more and more on the organization of the ego prior to what had previously been called the Oedipus or incestuous phase of development, that is, roughly before the age of three and a half years. These tendencies were greatly fostered by an increasing interest in the direct psychoanalysis of children. The first child-analyst in England, Mary Chadwick, started her specialist work about 1922. Between 1925 and 1927 two courses of lectures were given in Great Britain by a Berlin analyst, Melanie Klein, who had also specialized in child-analysis. By that time child-analysis had become a recognized specialty in Britain.

In any case, it was natural that interest should be focused on early stages of development. For although the Oedipus phase between three and a half and five years of age had been fairly accurately mapped out and although some working generalizations had been established regarding mental function in the first eighteen months of life, the gap existing between these hypothetical reconstructions and the established findings valid for later childhood called for attention. Ferenczi of Budapest and Abraham of Berlin had done extremely useful work in this direction, but their formulations were not completely satisfying. The main problem remained unaltered, namely, what are the fore-stages of the super-ego, i.e., before that period at which it is obvious that its main function is to enable the child to wean itself from its Oedipus longings, frustration and dependence. For until the age of roughly two and a half years, when it is first possible to establish a rudimentary “psycho-analytical situation” and thereby to check theories of mental development by direct psychoanalytical investigation of children, all such theories are of necessity based on hypothetical reconstruction and therefore give play to subjective factors. Obviously this state of affairs was calculated to give rise to dissensions and controversies, in which these subjective factors were bound to play an increasing part. And this is in fact what happened. A controversial period in the development of the British Psycho-Analytical Society set in. This was greatly accentuated by the development of a new school of child-analysis founded by Melanie Klein, who by this time had settled in England.

The earlier formulations of this school were received on the whole with eager acceptance by most members of the British Society. This was no doubt in part a reaction to the previous absence of any very new or striking contributions to psychoanalysis from within the group; but it was due also to a genuine desire to see the gaps in knowledge of the early ego and of pregenital development filled up. Briefly, the new ideas included a number of legitimate extensions of the theories of Freud and Abraham, including the existence of early forms of super-ego and the role of introverted sadism in modelling these early forms. On the other hand, the new concepts already showed a distinct anti-Freudian tendency. A true Oedipus phase and a true super-ego were postulated for the sixth month of life and it was further maintained that libidinal positions or primacies are called out by struggles with the aggressive impulses, that is to say, the destructive impulses are more creative in effect than the libido.

These tendencies to deviate from accepted Freudian theory became quite obvious in the later formulations of Melanie Klein on the subject of depression (Klein, 1935). It was laid down that a “depressive position” is organized from the third month of life. This, it was maintained, is the result of a love-trauma due to the infant's imagined greedy destruction of a real loving mother whom it really loves. This depressive position is based on an earlier ‘paranoid position’ in which the child is believed to suffer from anxieties due to the projection of its own sadism. It was also stated that all neuroses are different varieties of defence against fundamental depressive anxiety. The developmental importance of aggression rather than of libido was reasserted and it was maintained that unconscious fantasies occurring in the first few months of life exercise a far-reaching and uninterrupted influence on the development of the mind.

The Freudian distinction between the unconscious system and the pre-conscious system was considerably blurred; the concept of narcissism was dropped in favour of an imagined system of 'internal objects'; and auto-erotism was regarded not as a narcissistic phenomenon but as a system of occult allo-erotic satisfactions in which the part of the body masturbated is actually an internal object representing a former external object.

Had these assumptions been valid, they would have involved a drastic revision of Freudian theory. But their sponsor had gone too far. Although many members of the British Society espoused her cause in a most devoted manner, open opposition developed in other quarters. This was strengthened when, after the Nazi invasion of Austria, a large number of the Vienna group, led by Anna Freud, settled in London. Opposition to the penetration of the Society with Kleinian views became more organized and for a time the Klein group dropped their earlier and bolder suggestions that Freud was just a little antiquated and old-fashioned. Nevertheless the important issue—whether students of psychoanalysis were to be trained in Freudian or Kleinian views—could not be buried. Discussions on the matter were just reaching a crisis when the Second World War put an end to them for the time being. The situation then was that the Society was divided, though not openly, into three groups: a classical Freudian group, a Kleinian group and a "middle group" whose members, whilst accepting some of the earlier ideas of Melanie Klein, felt that her later formulations went too far.

Looking back it seems somewhat remarkable that the Kleinian deviations from Freud should not have led to more drastic action. It is now clear that the tendency of the later Kleinian theories is identical with the tendencies of those earlier schismatics, Jung and Rank. The Klein group follows Rank in attributing mental development, and all variations in mental disorder, to a traumatic situation occurring, not, it is true, at birth, but shortly after birth; it follows Jung in attributing dynamic and developmental power to archaic fantasies. The fantasies attributed to the suckling by the Kleinians do not differ from the archetypes of "original sin" which Jung regards as a product of the (Jungian) "collective unconscious".

### 3. Post-War Development

Towards the close of the war, when members who had evacuated London or had joined the Forces began to return, the Klein controversy broke out again. For 18 months a series of discussions on the subject took place, but the result was inconclusive. Many ex-Viennese members, dissatisfied with the state of affairs existing in the Society, had transferred to the United States of America shortly after the outbreak of war, and this weakened greatly the influence of the Freudian group. Hence, despite shattering criticism of their views, Kleinian members retained their membership of the British Society. The Society, whilst nominally unchanged, split openly into two main groups: Kleinian and Freudian. A middle group sat rather timidly and uneasily in the centre.

After prolonged negotiations an attempt was made, not indeed to bridge the gap scientifically—because the differences between Freudian theories on the one hand and Rankian and Jungian ideologies on the other are scientifically

irreconcilable—but to found some system of training which would obviate an official split in the Society. This, roughly, is the state of affairs at the present time. Students are at first taught only Freudian theory but after the first year their training is taken over by two groups teaching respectively Kleinian and Freudian theory and practice.

This camouflage arrangement, however, does not alter the situation and whether in the future the Society turns Kleinian or Freudian depends for the most part on the numbers trained by the respective groups. Mainly, but not exclusively: for after the war a new influence began to make itself felt in the British Psycho-Analytical Society. This was, in the first instance at any rate, a matter of policy rather than of science, and involved an almost formal rapprochement between psychoanalysis and psychiatry. Before the war, psychoanalysis and psychiatry reacted to each other with an aloof disregard bordering on contempt. Psychoanalysis would in fact have nothing to do with any body that did not profess exclusively Freudian principles. Suggestions that a closer contact might be made even with more eclectic medico-psychological clinics, such as the Tavistock Clinic, were frowned on. The Society itself contained only a sprinkling of young psychiatrists who had so far contributed nothing to psychoanalytical knowledge.

During the war psychiatry made spectacular advances in administrative authority. For no particular reason except that of favourable opportunity, psychiatry became a positive craze in the combatant services; and naturally once the war was over a number of young psychiatrists, who had whetted their appetite on psychiatry in the Forces, evinced a desire for psychoanalytic training. The Society for its part began to overcome its earlier distrust of psychiatry. To cut a long story short: under the influence of its psychiatric members, plans were put into effect to train a number of psychiatrists; more remarkable still, psychiatric-minded analysts took up administrative positions in the previously non-analytical Tavistock Clinic, now the Institute of Human Relations.

This new development may in course of time influence the trend of psychoanalytical thought in Great Britain. Psychoanalysis in Britain was not, as in the United States of America, an offshoot of psychiatric activity. It derived its support partly from lay cultural sources and partly from doctors who before and after the First World War were interested in the Freudian approach to medical psychology. In short, it developed in the European tradition of psychoanalysis in which psychiatry, it is true, played a part but never exercised controlling authority. The older lay traditions of psychoanalysis, which Freud, although himself a physician, did much to foster, are thus threatened with extinction. On the whole it is not a very happy development and does not augur well for future progress in psychoanalysis. No doubt it will contribute to the general efficiency of psychoanalytic training, for most of the early medical analysts and all of the lay analysts in Britain were deficient in psychiatric training. Nevertheless the specialized and restricted outlook of the psychiatrist does not qualify him to assume a directing role in psychoanalysis; in other words, the average psychiatrist has neither the education nor the cultural background necessary for psychoanalytical research.

Simultaneously with the development of this psychiatric bent, psychoanalysis has begun to play a larger part in the

practice of child guidance. Unfortunately a new branch of "child-psychiatry" threatens to offset any advantages that might accrue from this logical and essential development of psychoanalytic work. For if psychiatry exercises a too highly specialized and too rigid influence on adult psychoanalysis, it is still less suitable to act as a regulator of child-analysis. It is indeed imperative that the specialty of child-analysis should recruit its members from the most broadly orientated, soundly trained and scientifically disciplined groups.

#### 4. Present Situation

With this brief survey of recent developments in the British Psycho-Analytical Society it is possible to indicate the present scientific status of psychoanalysis in Britain. The Society is now divisible into four groups: (a) an orthodox Freudian group, (b) a Kleinian group, (c) a psychiatric group and (d) the remnants of the old "middle group" to which reference was made earlier. The orthodox group is concerned chiefly with the maintenance of Freudian standards of training and education, particularly in the field of child investigation. The Kleinian group has not produced any new orientations, although already its influence is responsible for a growing tendency to take the psychology of "internal objects" for granted and to regard it as the most important factor in mental development. We shall, I think, soon see a 'schizoid position' added to the 'paranoid' and 'depressive positions' and 'manic defences' of early infancy already hypothesized by the Kleinians. No doubt in course of time most of these absurdities will be either watered down or eliminated, but in the meantime they constitute a threat to the scientific development of psychoanalysis in Britain. In other countries they have received no support and a good deal of overt criticism. The position of the third or psychiatric group has already been indicated. As for the fourth and rather nondescript "middle group", there does not seem much hope that it will survive very long. People with a fanatical enthusiasm for a special point of view exert, in any case, more influence than those who, out of a wish for compromise, keep to the middle of the road. And although there is no scientific virtue in compromise, yet a strong middle group does serve to restrain the exuberance of enthusiasts.

On the whole, therefore, one can only hope that the first or orthodox group will extend its authority. Freudian principles are still vital to the development of psychoanalysis.

A similar comment can be made regarding the therapeutic aspects of psychoanalysis. Psychoanalytic therapy is not, as is often thought, just a matter of free association and *ex cathedra* interpretation. It depends on the development during analysis of what is called the 'transference neurosis'. Starting with a spontaneous transfer of friendly (or hostile) infantile attitudes to the personality of the analyst, the patient gradually "transfers his neurosis" to the analytic situation, thereby rendering it more amenable to analysis and liquidation. When this is achieved the analyst sets about liquidating also ("analyzing out") the transferences. This is what distinguishes psychoanalysis not only from hypnosis and suggestion but from all other forms of "analytical" therapy or again from mixtures of

suggestion and "analysis". Unless the transference is adequately analyzed, the whole process of therapy, and whatever therapeutic results may accrue, depend on a state of infantile rapport, in other words they partake of the essential nature of suggestion. Naturally the 'transference neurosis' occurs in classical form only during the psychoanalysis of the psychoneuroses, hysteria and the obsessions, which for that reason are often called 'transference neuroses'.

During the war, when military necessity dictated the use of short cuts in diagnosis, treatment or selection of personnel, a number of old methods were resuscitated and given more pretentious names; hence the use of 'hypno-analysis', 'narco-analysis' and at a later date 'group-analysis'. It is often assumed and sometimes explicitly stated that these constitute "advances" in psychoanalysis. The fact is, however, that they constitute merely advances in the technique, respectively, of hypnosis, narcosis and 'transference therapy'. They add nothing to our knowledge of psychoanalysis proper and in fact act as obstacles to the carrying out of classical analysis. Whether they produce results more quickly remains to be seen, and is in any case beside the point. No one ever suggested that an analysis should be evaluated by temporal measures. And as Freud, anticipating that some time or other necessity would lead to a mixing of methods, once remarked: the quickest way to carry out an analysis is to do it properly, i.e., in accordance with psychoanalytical principles. No doubt psychoanalysts have tended to neglect Freud's conservative views on the therapeutic applicability of psychoanalysis to cases indiscriminately selected, and have only themselves to blame when, goaded by the intractability of many non-neurotic cases (e.g., character disorders, psychoses and perversions), they hanker after quicker methods. But it is inherently unlikely that any method which canalizes rather than analyzes the transference will in the long run prove more efficient or permanent in effect than psychoanalysis proper.

But when all is said, the present is an interesting phase in the history of psychoanalysis. However absurd some of the hypotheses recently advanced may have been, there is no doubt that the focusing of interest on problems of early ego-development and on the organization of mind during the phase of 'primary identification' (i.e., at the stage before the 'self' and the 'not-self' are accurately differentiated), will in the long run produce results of value both diagnostically and therapeutically. It will involve, as I have suggested in my 'theory of nuclear development of the ego', a molecular rather than a 'gestalt' approach to the subject; or rather, it will involve a distinction between rudimentary and organized gestalt-patterns of the unconscious (Glover, 1932a, 1932b, 1933, 1943).

What psychoanalysis needs in the future is what it has always sorely needed, an accession of scientific workers, who must, it is true, be able to conduct therapeutic analyses—that is essential—but also whose interest in research or in the formulation of new theories is disciplined by scientific controls rather than regulated by "intuitions", which are often little more than subjective reactions. If psychoanalysis could rally to its ranks the numbers of young, intelligent and imaginative men and women who flock to the service of physical science, progress in research would no doubt be spectacular. But alas for the prospect, the budding physical scientist may make a good academic or laboratory

### 1. History of Psychoanalysis in Great Britain

The interest of several pioneers in psychoanalysis, of whom Ernest Jones was the chief, led to the formation of the London (now British) Psycho-Analytical Society before the First World War. In 1913 it was affiliated to the International Psycho-Analytical Association. In 1919 Jones, who was President of the Society until 1943, founded the International Psycho-Analytical Press for the purpose of publishing books and journals. In 1924 the Institute of Psycho-Analysis was constituted in London as "a company not for profit" with memorandum and articles of association giving wide powers in clinical and scientific matters

\* [See also article by Edward Glover in this number (BMB 1297).—Ed.]

and the legal power to receive bequests but not to distribute profits. The Institute provided a clinic for the treatment of needy patients, and a library and courses of training were also inaugurated. One of the Institute's first functions was to take over the International Psycho-Analytical Press, and arrangements were made to carry on the work of publishing books and the *International Journal of Psycho-Analysis* and its supplements. The Journal has been issued continuously since 1920.

The Institute of Psycho-Analysis is therefore an organization which deals chiefly with external relations, with publications, with training and with the maintenance of a clinic, The London Clinic of Psycho-Analysis. The British Psycho-Analytical Society is concerned solely with organizing meetings, held bimonthly, for the discussion of scientific matters; its membership in 1948 consisted of 72 medically qualified members and associate members, and 35 non-medical members and associate members. Associate members are elected to full membership when they have made a contribution to the theory or practice of psychoanalysis.

#### *a. Methods of Training*

Perhaps the most important function of the Institute is that of training future psychoanalysts. The plan of training is similar to that organized by other psychoanalytic training institutes elsewhere in the world, and consists mainly of three parts. A student begins his training by undergoing a personal analysis, and then, usually after a few months, he is ready to start attending lectures and seminar courses in theory and practice. The didactic courses continue throughout three academic terms for three consecutive years. Some time after commencing didactic work the student begins the psychoanalytic treatment of patients, under the supervision of senior psychoanalysts. Supervision continues for two years.

When trained to the satisfaction of the Training Committee, the student is proposed for associate membership in the British Society of Psycho-Analysis. The last annual report of the Institute states that 59 students were in training in June 1948, 42 of whom were medically qualified. The main scientific background of the non-medically-qualified students is in psychology, sociology or biology (some students at the Institute being medical students at the time of their psychoanalytic training).

## PSYCHOANALYSIS: THE FREUDIAN POSITION

*Continued from page 30*

psychologist but he does not as a rule make a good psychoanalyst. Hence it is necessary for psychoanalytic institutes to go out into the highways and byways of cultural activity to seek promising recruits. These, when found, must be suitably subsidized to stand the financial strain of a combined psychoanalytical and medical education, and, later on, prevented by appropriate

rewards from choosing the path of professional success rather than the less lucrative road to scientific discovery. Psychoanalysis, which seeks to penetrate the mysteries of cultural development, must become and remain a cultural as well as a therapeutic or professional pursuit.

Edinburgh and Manchester are the other centres in Great Britain where psychoanalytic work of any intensity has been carried on. For a period during the war there were sufficient psychoanalysts in Manchester to begin courses of training in association with the London Institute.

#### *b. Extension to other Fields*

During the early years of psychoanalysis in Great Britain most psychoanalysts were fully engaged in private practice and the only psychoanalytic treatment available, other than in private practice, was at the London Clinic of Psycho-Analysis. The early British psychoanalysts taught psychoanalysis chiefly by their writings, but occasional public or medical lectures, and the work of Forsyth, Hart and Stoddart at three London medical schools (Charing Cross, St. Thomas's and University College Hospitals) and the work of Professor Flugel in the Department of Psychology, University of London, had their effects. During the past 15 years the situation has changed. Several qualified psychoanalysts have begun work in fields other than psychoanalysis itself—in mental hospitals, in child guidance clinics, in psychiatric out-patient departments, and in a clinic associated with the Institute for the Scientific Treatment of Delinquency. Psychoanalysts have taken part in teaching, chiefly at the Institute of Psychiatry, Maudsley Hospital, the Tavistock Clinic, the Institute of Education, the London School of Economics (training course for psychiatric social workers), and at the Paddington Green Children's Hospital, all in London. One British hospital (the Cassel Hospital for Functional Nervous Disorders at Richmond) has, since its foundation, actively sponsored intensive psychotherapy and at present is the chief hospital in Great Britain where treatment is mainly psychoanalytical.

The foregoing is a brief survey and will be elaborated later in this article by a more detailed sketch of psychoanalysts' work in Britain.

Early in its history psychoanalysis attracted workers who later developed theories and beliefs incompatible with those of their colleagues. Such workers have resigned from the analytic organizations and have worked with other groups or formed their own groups. Outside Great Britain this happened with Adler, Jung, Rank, Reich, Stekel and others. In Great Britain such difficulties have been few in the history of the British Psycho-Analytical Society. The development of beliefs and interests divergent from those held by the Society led to the resignation of Miss N. Searl about 1937 and of Dr. Edward Glover about 1944. Searl had made important contributions to child analysis and to the psychopathology of early aggression—chiefly on the effects of screaming. Glover had for many years played an important role in the work of the British Society and had contributed perhaps most notably to the problem of ego development by his attempts to describe "primary ego nuclei"—the later integration of which leads to the formation of the infantile ego. Searl's resignation from the Society was based on the development of a predominant interest in parapsychology; Glover's was based on his belief that the divergent views held by different members of the Society were inimical to good scientific work and to the training of the next generation of British psychoanalysts. He disagreed strongly with the findings and views of many members of the Society regarding the origin of depression

during infantile development—findings which were first published by Melanie Klein in 1935.

## 2. General Clinical Activities

Before going into detail concerning those aspects of psychoanalytic work in Great Britain in which most progress has been made and where divergences of theory and practice are active, it may be well to broaden the description of work done by analysts in fields other than analysis itself.

Effective work by psychoanalytically trained workers has been most definite in the field of child psychiatry and child guidance. Bowlby's work (1948) on thieving in juveniles has demonstrated the inability of persistent offenders to form affectionate attachments. He has pointed out that in the vast majority of thieves with such inhibited affections there has been prolonged separation of child and mother during the first five years of life. Friedlander (1947) surveyed the problems of delinquency, as they are met in child psychiatry, in her recent book, *The psycho-analytical approach to juvenile delinquency*. The group working with Bowlby (who is in charge of the Children's Division of the Tavistock Clinic) are experimenting with the effectiveness of treatment by interviews of a psychoanalytic type held relatively infrequently, i.e., once or twice weekly.

The work of the late Susan Isaacs, through her position as a teacher in the Institute of Education, University of London, brought analytic principles to the fore. The great loss her recent death has been to British psychoanalysis will be only partly redeemed by her numerous clear expositions of psychoanalytic problems. After a period of work studying child development she became a psychoanalyst of children, closely associated with Klein. Her writings on the detailed role of infantile and childish fantasy-play in development will be a source of value for years to come (Isaacs, 1948).

Anna Freud and the group of workers associated with her have contributed valuable observations on childhood development as seen in deprived children later cared for by her and her colleagues in a London nursery during the war years (Freud, 1946; Freud, 1947; Freud & Burlingham, 1942; Freud & Burlingham, 1943).

Through their interest in child psychiatry the attention of psychoanalysts was turned to the problems of delinquency. In 1931 the Institute for the Scientific Treatment of Delinquency, London, was founded. From the first, several psychoanalysts were actively interested in this field and are continuing to work at the Clinic started by the Institute, now part of the National Health Service hospital organization.

Mental hospitals have attracted a few analysts. Stengel has continued to apply psychoanalytic principles to his work and has reported observations which could be made only on institutionalized cases of psychoses (Hemphill & Stengel, 1940; Stengel, 1945; Stengel, 1948; Stengel & Steele, 1946). At present, numerous students at the Institute of Psycho-Analysis are spending most of their time working in mental hospitals and it is to be hoped that a proportion of these will continue work with patients whose illnesses are so severe that treatment in a mental hospital is necessary. Most of the staff of the Cassel Hospital for Functional Nervous Disorders are either qualified psychoanalysts or students of psychoanalysis. This hospital

provides the one example in England where psychoanalytic treatment is being used in the in-patient field. Scott (1948) has reported his work with manic-depressive patients at this hospital.

In Great Britain (in marked contrast to America) none of the non-state-aided mental hospitals, where patients pay a fee approaching the maintenance charge and where over the years a very considerable endowment has often been built up, has as yet fostered psychoanalytic work.

The Second World War stimulated several psychoanalysts to work with groups of patients (Bion & Rickman, 1943; Foulkes, 1946, 1948; Foulkes & Lewis, 1944; Wilson, Doyle & Kelnar, 1947). The experimental work which Bion (1948) is continuing is perhaps the most interesting, in the sense that it attempts more fully to discover to what degree an analyst can contribute to the activity of a group of people seeking help if he adopts the same attitude to the group which he would to an individual patient.

At present, British psychoanalysts teach psychoanalysis only at the Institute of Psycho-Analysis. The last report of the Committee stated that 24 psychoanalysts were active in conducting personal analyses, and in supervision of students' psychoanalytic treatment of patients. Elsewhere, courses in normal and abnormal development in childhood, based on psychoanalytic findings, are given to teachers in training, to student psychiatric social workers and to other workers in the fields of child-care. Teaching in psychoanalysis as applied to psychiatry is unfortunately restricted to postgraduate training—none of the undergraduate medical schools at present has a psychoanalyst on its teaching staff, although Winnicott has for years taught the application of psychoanalytic principles to paediatrics at the Paddington Green Children's Hospital, London.

### 3. Recent Progress in Psychoanalysis

War, as most scientists agree, decreases the rate of scientific discovery, but greatly increases the rate of application of discoveries already made. It has had this same effect in the field of psychoanalysis. More than a quarter of the medically qualified psychoanalysts were engaged in applying their psychoanalytic knowledge in the wider fields of work into which they were drawn by the war, and of the remainder, few were able to continue analytic practice as intensively as before the war. Nevertheless, training at the London Institute of Psycho-Analysis continued during the war years and scientific meetings were held regularly. Luckily, circumstances allowed many of those senior analysts, whose contributions will be discussed shortly, to continue their scientific work.

During the early years of psychoanalytic work in Great Britain, most scientific meetings of the Society consisted of discussions and elaborations of the work of the European psychoanalysts. Nevertheless the five editions of the collected papers of Ernest Jones show how many original contributions to theory and practice were made in this country even in this early period (Jones, 1948).

#### *a. Child Analysis*

The fundamentally new theoretical conceptions and new aspects of practice which were brought before the British

Society were those of Melanie Klein. All, except her latest paper, are included in two books: *The psycho-analysis of children* (Klein, 1949) and *Contributions to psycho-analysis, 1921-1945* (Klein, 1948). Freud had early pointed out the importance of applying analytic understanding to the developing child, whether the child showed a neurosis or not. Several European workers, the chief of whom was Anna Freud, carried out psychoanalytic treatment of children, although some significant modifications were considered necessary, chiefly in the direction of fostering a positive feeling in the child for the analyst and in assuming to some degree the role of a teacher. Klein consistently attempted to modify the analytic situation in a minimal way, the chief modification being the provision of a room in which simple toys, a couch, chairs, a table, a sink with water, etc., were present. She showed how, by the observation of children's play, a technique of psychoanalytic treatment could be developed as early as the third year; and further, that the analyst could maintain the same attitude to the spontaneous play of the child as he habitually did to the verbal productivity of an adult during analysis. It became apparent that a child would accept this situation, just as the adult, as Freud had discovered, accepted the analytic situation. It was found that the sequence of activity or play, whether it included much speech on the part of the child or not, could be understood and interpreted to the child in such a way that his subsequent behaviour or speech gave indications of the correctness or the falsity of the previous understanding and interpretations.

Work with children led to increased knowledge of unconscious mechanisms which are prominent during the first years of life. In particular the increased knowledge of introjection and projection mechanisms, of infantile omnipotent fantasies and of the almost lifelong importance of 'object relationships' led not only to an increased understanding of the child, but also to a realization of the implications of these mechanisms in the neuroses of later life. The implications of such mechanisms for an increased understanding of adult and childhood psychoses, especially manic-depressive psychoses, may in the long run be a most important stimulus to further research in treatment.

#### *b. Aggression and Origins of the Super-Ego*

The extension into infancy of problems which had previously been thought to begin first in childhood has led to a review of the origins of the Oedipus complex and of the origins of the super-ego. Much evidence has been accumulated to show that the father or his substitute appears as a rival for the breast and that the father (or his substitute) is taken by the infant as an early source of substitute gratification when the mother frustrates the infant. Both these factors lead to the development of the infantile triangular situation, when oral love and oral hate are dominant and before genital feeling comes to play the predominant role that it does during the next few years, during which the classical genital Oedipus complex develops. Interrelationships between aggressive and libidinal activities from the earliest age had to be assumed, as continued work with infants and children (and later, work with adults whose illnesses were severe and in many cases psychotic) accumulated. Problems began to arise in the analytic situation which previously had been recognized only in

severe psychoses; in some cases these problems could be beneficially affected by continued analysis.

Considerable divergence of opinion regarding the origin of aggression still persists. Klein considers that the intensity of infantile aggression is such that it can best be understood as evidence of the correctness of Freud's formulations of a "death instinct" which is projected on to frustrating objects in order to preserve the ego. Although many continue to accept Freud's view, others try to understand infantile aggression in terms of an instinctive response to frustration of libidinal wishes, either by environmental agencies, or by sources originating within the body. Others try to understand the content of aggressive activity as a disorganization of libidinal activity in the presence of non-satisfaction, whether the source of the non-satisfaction lies outside or inside the body. By the death of M. P. Middlemore, British psychoanalysis lost a keen observer, but not before she had published observations of the variability of initial satisfactory and unsatisfactory sucking activity (Middlemore, 1941). A continuation of her work should help to solve some of the problems regarding the relationship between libido and aggression.

### *c. Origins of Depression*

Perhaps the most important theoretical formulations introduced by Klein, which have been confirmed by many analysts, concern what she at first called 'the depressive position'. Fundamentally it was an extension of the previous work of Freud and Abraham to a point where the connexion between normality and abnormality is easily seen, and to a point in development where grief and depression are first added to the earlier emotions of love, hate and fear. Before this there had been great difficulty in describing how any individual came to develop what can only be called the normal human capacity for disappointment, sorrow and grief.

The following outline attempts to picture the problem as it is seen by many British psychoanalysts today. To put simply how disappointment can arise for the first time, it is necessary to describe how the infant develops to a stage which allows disappointment to appear. Regardless of what view is held about the source or nature of instinct, it is obvious that from an early age the infant breathes air, sucks milk, passes water and stools, moves about, and sleeps. These activities may be generally satisfying. If any are unsatisfactory, the infant becomes angry. Regardless of how severe or wide-spread his anger may be and regardless of how many organs he uses to vent his anger, he will first show his rage in the unsatisfied part; for instance, if breathing is unsatisfactory, he will breathe angrily; if sucking is unsatisfactory, he will suck in rage. From the earliest age each pleasant or angry activity has a direction, namely, an interchange between what comes to be called later the outer and the inner world—the infant breathes in or out, he swallows or vomits.

Only slowly in the infant's developing scheme of things are "people" included in the form in which he will know them later in childhood. Earlier his world consists of what he will later know as parts of people—breasts, faces, hands, etc. Equally slowly is a knowledge of a "self" as a whole person or other people as whole people developed. Only slowly are the distinctions which are later called sen-

sations, illusions, images, memories achieved. Somewhere along this line of development crucial points may be noted and at one of these crucial points disappointment and depression become possible for the first time.

To describe adequately the onset of depression some aspects of the sequences just mentioned must be given in more detail. Hunger may lead to sucking a breast and to experiencing pleasure. Through the acts of breathing, sucking, smelling, touching, swallowing, the feeling of a "good" something going into the inner world occurs; in the literature of analysis this something is usually referred to as an 'object'. During or following such a pleasant experience, the infant may empty his bladder or bowel, or sleep with pleasure, and may as yet not clearly appreciate that there is an object associated with the experience of evacuation. Nevertheless there is a beginning realization that an exchange between the outer and inner worlds, and between the inner and outer worlds, can occur and that it can be good.

On the other hand, hunger may not be followed by a satisfying, pleasant sucking. Instead it may be followed by bellowing and gnashing of toothless gums, by a spreading rage, and by the emptying of bowel and bladder during this rage. The accompanying feelings appear to be that a "bad" interchange is taking place between the inner and outer worlds, and any differentiation between 'objects' in either the inner or outer world is into many "bad" objects. Such a fit of rage may of course be followed or interrupted by a satisfactory experience, but such a satisfaction will be different from what it would have been had not a bout of anger preceded it. Such experiences are repeated many times in slightly different forms during development. The series of pleasures, dissatisfactions and rages leads, on the one hand, to memories of the inner and outer world in which infantile fantasy of a loving type has had free play, and, on the other hand, to memories of infantile hateful experiences in which persecutory feelings are important.

Sooner or later sufficient integration occurs for the infant to realize that the memories of the loving, satisfying breast and the hating, frustrating breast are of one and the same breast; and that the happy sucking mouth and the angry, frustrated, hungry mouth are the same mouth. The time of such an event will vary with the degree of maturity at birth, with the intelligence of the infant and with the quality of his previous emotional development, but often occurs during the first year.

This realization—that maximal love and maximal hate can be expressed by the same bodily organ and can be felt towards the same object, and that this object can be both satisfying and frustrating and can appear to be both loving and hating—is one of the crucial points of development. On analysis, feelings of disappointment and depression and grief and guilt all appear to be different ways of discussing the implications of this crucial phase of development. If this new feeling of depression is tolerated, if the belief is that love is greater than hate, and if love can be used to overcome, to annul, or repair the effects of hate, the infantile type of resolution of disappointment and depression occurs and the way is laid for the development of a normal appreciation of the varieties of human experience that are to appear during the later stages of development. On the other hand, an incomplete tolerance of this situation may

lead to the many forms and symptoms of abnormal depression of all degrees of severity. If rage and hate are something greater than love, if the memories of the many hateful acts, impulses and fantasies outweigh those of love, then there arise hopelessness and depressive anxieties connected with the belief that only bad can be done and only badness is to be expected of one. At its extreme, this may lead to a situation in which the ego will have to be destroyed to protect anything that is good or anybody who is good from one's own badness and rage. The self may be destroyed actually in suicide or symbolically in a temper tantrum or a fit.

Gradually, as more integration occurs, the belief in a whole continuing self and in whole continuing people leads to the multifarious variations in the conscious conscience and the unconscious conscience; these in turn give rise to the series of changes which lead to the formation of the adult super-ego. Gradually more details of the origins of the super-ego in the early introjections of loved and hated objects are becoming apparent.

The behaviour and speech of the depressed person demonstrate his attempts to discover more satisfactory ways of dealing with the more or less conscious realization that his hate for the same person is greater than his simultaneous love for that person, without at the same time denying that it is he himself who both loves and hates or that it is the same person whom he both loves and hates. At the period when such an integration first occurred, the predominant impulses, facts and fantasies were connected with the mouth and respiration, but nevertheless activities of other organs played a role. Although from a very early period of life

some organ systems play a predominant role, the fact that all organ systems which later can reach consciousness in their functioning also play a significant role has much to do with the finding that the symptomatology of depression has so many ramifications in the personality.

The scheme just outlined, when applied to the complex symptomatology of infantile, childhood, adolescent, adult or senile depression, has added greatly both to the understanding and treatment of depression.

#### 4. Future Prospects

Further work is naturally leading to an interest in the types of disorganization or dissociation or splitting seen in various schizophrenic states or in schizoid personalities, and active discussion concerning these mechanisms is going on in the British Society at present. In the background there are problems which are only beginning to be attacked, namely, masochism associated with various types of organic disturbance, narcissism, and the complicated states of defect and the serious types of schizophrenic inhibition and disorganization. Behind all such interest in new problems stand two facts. The first is the large number of students who are willing to spend sufficient time and energy to equip themselves with an adequate training to co-operate later with their teachers. The second fact is the inroad which psychoanalysis has begun to make into the understanding of sequences of behaviour unassociated with many words—as is so often the case in interviews with neurotic children and with psychotic adults and children.

The last twenty years have witnessed a profound revolution in the treatment of the mentally ill. On the one hand there is wider knowledge about human motives and psychogenesis. This has led to the recognition of the importance of emotional tensions within the family and in marital and group relationships, which, while they may contribute little or nothing to our knowledge of the psychopathology or structure of the severer psychoses, nevertheless throw much light upon precipitation and prognosis. On the other hand, technological advances in biochemistry, physics and electronics have promoted an era of experiment, based upon speculation about the somatic aspects of mental disorder.

### 1. The Different Methods and their Values

It has been said (Lewis, 1945) that there are many physical methods used in psychiatry besides the induction of convulsions, insulin coma and frontal leucotomy. These three and their modifications, however, share characteristics which separate them from continuous sleep, malarial or penicillin therapy, thyroid administration, and many others. The latter treatments have a rationale based on the known etiology of the condition treated. They are directed most specifically at a pathogenic agent, faulty metabolic events, or as symptomatic treatment to allay the vicious circle of anxiety and its physiological accompaniments. The three first-named techniques—generally called “shock” treatments—are, however, empirical and have been developed

from theories, already proved erroneous, about the pathophysiology of mental disorder. All involve the production of unconsciousness in the patient: all are potential threats to the patient's life and carry attendant risks: all produce, but in varying degree, profound changes in the central and autonomic nervous systems.

The value of such treatments in the large range of functional psychoses is undoubted. Statistics abound which demonstrate the value of insulin comas in schizophrenia, of convulsion therapy in the depression of later life, and of prefrontal leucotomy in all manner of conditions. In the last named, the statistical evidence is less weighty, although the Board of Control Report (1947) carefully assesses the results of the first 1,000 leucotomy operations in Britain. Many eminent observers have ascribed their good opinion. Thus, Sir David Henderson in his presidential address to the psychiatric section of the Royal Society of Medicine said:

I at least am satisfied from my personal experience, and no one can rob me of it, that in leucotomy we have a means of benefiting many persons to such a degree that, irrespective of a failure here and there, a great advance in the treatment of otherwise intractable conditions has been effected.

Dr. Desmond Curran at the conclusion of the Croonian lectures (1948), which he devoted to the subject of prefrontal leucotomy, and the manuscript of which he has kindly allowed me to see, said:

Remarkably few people are worse for the operation and if it is felt that in many instances the best that is achieved is a poor one it will be found that such a view often arises from an inadequate appreciation of the deplorable state and prognosis of the preoperation condition. In many instances the best that is achieved is very good indeed.

Although there appears to be general agreement that insulin comas are of value in schizophrenic states and only in them, there is much less specificity for the other methods. Thus, convulsion therapy is known to produce remission not only in depressive states but also in some schizophrenic illnesses, and the operation of prefrontal leucotomy has been performed with benefit in schizophrenic, depressive and obsessional states. Numerous attempts have been made to isolate the personality types, the constellation of symptoms, and the various factors which enable a selection of the correct treatment to be made for the individual patient. Nevertheless, despite these efforts, physical treatment in psychiatry remains for most patients an experimental procedure and often patients are subjected to each method in turn. Posterity may well consider that these treatments, in their present form at least, are very crude and that the patients' nervous systems are subjected to unnecessary traumata. Research will in time very probably alter this; the techniques as we know them may well be superseded by measures which bear no outward resemblance to those in use today. Nevertheless, it is clear that in the massive organismal insults to which patients are at present subjected, there lie hidden some therapeutic principles, which act upon known or unknown psychological or physiological mechanisms and which it should be our earnest endeavour to discover.

The possible approaches to this subject are necessarily predetermined by the conceptions concerning human behaviour, normal and abnormal, held by the investigator. “Explanations” of the benefits of, for example, convulsion therapy vary from the “purely” psychological to the

"purely" physiological, with many intermediate theories. In the present state of our ignorance none can be neglected, although it is always necessary to consider such formulations against the background of what is known with certainty about the etiology of the psychoses. The subject offers a wide variety of approaches. In the first place, the important modification in techniques instituted in recent years has thrown some light upon what is essentially therapeutic, and what unnecessary, in the treatments. Next, studies of the psychological and physiological characteristics of the patients benefiting can be compared with similar studies of those not benefiting. Thirdly, the immediate psychological and physiological effects of the treatments may be examined; and fourthly, a search made for any lasting effects in the patients resulting from the various procedures.

## 2. Modification in Technique

Two tendencies are at present discernible. In the one, a greater refinement of technique leading to less damage to, or interference with, brain functions is apparent. In the other, the attack upon these functions is more massive and the immediate physical and psychological effects more profound. Thus, on the one hand we find the development of limited forms of the leucotomy operation, or of ways of inducing convulsions with the minimal dispersion of electrical energy in the brain; on the other hand, the advocacy of prolonged insulin comas, of multiple convulsions within the space of hours or days, of prolonged electro-coma and of the largest leucotomy cuts. These divergent tendencies probably only reflect the present uncertainty regarding the mechanisms of action. More important, however, is the increasing realization of the unspecific therapeutic effects of the treatments in themselves. Thus, it is now common practice to combine insulin comas with induced convulsions, and there is increasing emphasis upon the importance of psychotherapy in both treatments.

### *a. Insulin Coma Therapy*

While there is no specific treatment for schizophrenia, the benefits of Sakel's hypoglycaemic technique (Sakel, 1935, 1938) in promoting remissions, particularly in the early cases, is undoubted. There have been few important modifications in this, the first of the "physical methods", in recent years. Modified insulin therapy, in which smaller doses of insulin are used and the hypoglycaemia is terminated before coma, has been extensively used for correcting the physical effects of emotional exhaustion, in promoting rehabilitation in the acute neuroses seen in war and in creating a favourable atmosphere for psychotherapy, but it has no place in the treatment of schizophrenia, or other psychoses. In these it seems necessary to induce comas. Most observers favour prolonged comas (Horwitz & Kalinowsky, quoted by Wilcox, 1948; Sargant & Slater, 1948), and many comas, even when improvement begins early in the treatment (Freudenberg, 1947).

Convulsions, either induced by the electrical method or by metrazol, are recommended as adjuvants by many. These are given either before the insulin coma or during the early stages of coma, and are particularly valuable in the first year of the illness (Sargant & Slater, 1948). It is, of

course, known that both treatments individually prove increasingly ineffective as the duration of illness lengthens. Increasing importance is placed upon psychotherapy during insulin treatment. In fact, there is doubt whether the active interest in the patient, that is, the positive therapeutic atmosphere of the insulin unit, is not more important than the somatic effects of coma. There can be no doubt that the frequency of remissions rises significantly when the treatment is given by a clinician who devotes his whole energies to the insulin unit, who combines active psychotherapy and social and occupational rehabilitation with the formal production of comas every morning. Levy & Perry (1947) recommend sessions of psychotherapy under sodium amylal narcosis three times a week during the course of treatment. The common observation of the greater rapport which can be obtained with the schizophrenic immediately after recovery from his morning coma, together with the importance given to psychotherapy, may well lead to the conclusion that the mechanism of recovery after insulin coma lies in the production of a state in which the patient is prepared for psychotherapeutic help.

### *b. Convulsion Therapy*

Variations in the characteristics of the electrical current have been made to find the best method of inducing a convulsion with minimal transmission of energy to the brain, to minimize the mental confusion and memory changes following the convulsions and to reduce the initial jolt to muscles and bones which is consequent upon the fact that maximal stimulation occurs at the start of the standard Cerletti-Bini technique. The instrument developed by Strauss & MacPhail (1946) delivers a measured stimulus with a condenser discharge which is interrupted by a high speed oscillator. The pulses can be arranged to be either monophasic (uni-directional) or diphasic (alternating), but the initial pulses are maximal and decline as the condenser discharges. Therefore the tonic phase of the convulsion is still maximal at the start. Nevertheless, the convulsion is milder, recovery is more rapid, and there is less confusion. Liberson (1947), Wilcox (1948), Tietz (quoted by Wilcox, 1948) and others have experimented with variations in the duration of each stimulus, and in the number, time and grouping of stimuli. These have been fully reviewed by Wilcox (1948). In the Wilcox-Reiter technique, monophasic 60 cyc./sec. current is used with short intervals between each pulse and larger intervals after each three pulses (50 msec.). This gives about 35 groups of pulses every second. The pulse amplitude is much less than in the Cerletti-Bini technique, but is itself modulated; the total duration of stimulation is about ten times longer. The amount of energy dispersed in the brain is therefore much less. Instead of electrodes on both temporo-frontal regions, the positive electrode is placed upon the vertex and the negative upon the temple. With this method, Wilcox finds that the memory changes are much less, that the persistent changes in the cortex, as shown by the electroencephalogram (EEG), are also less and that apnoea is reduced to a minimum, although the therapeutic effects are no less than with the standard technique.

Liberson (1948) introduced a modification of stimulus duration. Using 120 sec. square waves of brief duration (0.5-0.7 msec. compared with 8-10 msec. for the other

methods) with a total duration of 1–1.5 sec., convulsions are induced with an even smaller dispersion of electrical energy in the brain. Liberson claims even less memory disturbance from his technique, but the patients have greater fear of the treatments in consequence of the reduced amnesia. Occasionally the patients awaken before the convulsion is over and for this reason Liberson recommended a pulse duration of at least 0.5 msec.

Tietz (1947), Medlicott (1947), and Paterson & Milligan (1947) have utilized electrical stimulation to produce a prolonged tonic spasm, suppressing the motor effects of the clonic phase and by continuing the stimulation at a lower level, maintaining the patient in a state of unconsciousness, misnamed "electronarcosis"—a better term would be "electro-coma". In this technique, the current rises slowly from zero to 200mA, a level below that used for convulsion, in 1 to 3 sec., and this level is maintained for 30 sec. The current is then slowly reduced to restore respiration, after which it is raised again to 110–140 mA. After 7 minutes it is slowly reduced to zero, after which the patient regains consciousness. The advocates of electronarcosis claim that confusion and memory changes are less than with the standard convulsion techniques, but admit that dread of treatments may be serious.

Initial cardiac arrest occurs in both these techniques, but secondary bradycardia occurs only in electronarcosis. The subsequent later tachycardia continues longer in electronarcosis and the rise in systolic and diastolic pressure is greater and persists longer. Bowman & Simon (1948) emphasize the importance of the "suppressed" clonic phase in electronarcosis, believing it to be important in the therapeutic effect. They doubt whether the results, without this phase, would be any better than those obtained from the "petit mal" reactions of "missed" electric convulsions, which are known to be minimal. They question whether the therapeutic results would not be equally good if the current were turned off at the end of the 30 sec. initial period. The intensive convulsion therapy (4 treatments a day) advocated by Milligan (1946), Kennedy & Anchel (1948), Tyler & Löwenbach (1947), Thorpe (1947), and Geoghegan (1946) for psychoneurotics, manics and schizophrenics produces a profound confusional state with incontinence and a delirium resembling the post-traumatic state. This illustrates a tendency away from those efforts, already cited, to produce minimal brain damage or dysfunction. The complete non-specificity of the cases treated, and the uniform confusional state induced, suggest that the efficacy lies in the masking effect of the latter. It is as yet too early to know whether these massive insults to the brain will find a place in psychiatric therapy. Clearly the effects go far beyond those produced either by the standard electro-convulsant method or by electronarcosis. No proper appraisal of the physiological or psychological aspects has yet appeared, and statements alleging the absence of risk must be accepted with caution.

Some of the minor modifications in the technique of giving convulsions, aimed at reducing complications, are relevant. Curare, which reduces the motor convulsive activity, prevents the rise of venous pressure; the inhalation of oxygen minimizes anoxia but has no effect upon the efficacy of the convulsions. When anxiety and apprehension are reduced by barbiturate sedation or abolished by pentothal anaesthesia, the treatment remains effective.

On the other hand, the methods of mechanical restraint in common use, including elaborate jackets which must enhance anxiety, have equally little effect upon efficacy. Subconvulsive stimulations, utilizing the Reiter and Liberson techniques with different electrode placements, are reported by Wilcox (1948): Amnesia for a few minutes, followed by confusion, has no therapeutic action. Such stimuli through the frontal poles produced anxiety, but if combined with preceding stimuli to Brodmann's area 38 to produce amnesia, some clinical improvement occurred, though this was not comparable with that after the full convulsion.

### *c. Prefrontal Leucotomy*

In the original operation performed by Almeida Lima of Lisbon in 1935, at the suggestion of Egas Moniz, the object was to sever as much as possible of the white matter in the frontal lobes in a plane just anterior to the frontal horns of the ventricles. This object was pursued by Freeman & Watts in America and by McKissock, Radley Smith and other neurosurgeons in England. Until recently Freeman (quoted by Mayer-Gross, 1948) has aimed at the greatest possible severance. The clinical effects of this procedure, apart from any amelioration of the psychosis, are those of frontal lobe damage described after head injury. Mayer-Gross (1948) has summarized them concisely:

In the emotional field: euphoria, fatuous equanimity, absence of finer emotional response, rudeness and tactlessness; in the motor field: hyperkinesia, restlessness, distractibility; and in thinking: turning towards the 'concrete', impairment of 'synthesis' and lack of insight. After leucotomy these symptoms may be much milder than after gross cerebral injuries in clinical material; but the difference is only one of degree.

Other immediate but transient effects are bulimia, disturbance of memory and retention, apathy or lack of emotional inhibition.

A contrary view of what determines the therapeutic effect has led to the experimental trials of partial or selective cuts of frontal white matter, producing a local severance of certain cortical areas from their projection nuclei in the thalamus. A vertical cut, "isolating" the orbital surface, is advocated by Dax & Radley-Smith (1943, 1946, 1948), Hofstatter, Smolek & Busch (1945) and Reitman (1946) for the emotionally apathetic, dull, introverted patient. The efficacy of this orbital leucotomy is believed to be due to the development in the patient of the symptom triad of euphoria, hyperactivity and extraversion—a syndrome known to occur after orbital cortex ablations and lesions. Dax & Radley-Smith (1943) believed that, on the other hand, the upper section cuts reduced psychomotor overactivity. It is possible that these partial effects, which obviously have therapeutic significance, contribute to the total picture of the frontal lobe syndrome produced by the total operation.

The disturbing results of too great a destruction in the brain have led to other partial forms of the operation. Freeman (1948) now favours the transorbital approach proposed by Fiamberti, which severs only those fibres in the frontal polar regions, thereby isolating cortical areas 9 and 10. Actual excision of the frontal poles has been performed at open operation by other workers, as well as undercutting of the cortex and "topectomy", "areaectomy" or "fractional resection" of cortex, with minimal interference with white matter. At the International Congress

of Psychosurgery in Lisbon, 1948, Wycis, Freed & Spiegel demonstrated a stereotaxic instrument used for producing partial destruction of the dorsomedial nucleus of the thalamus by an approach from above. The rationale of this procedure lies in the fact that this is the main thalamic nucleus projecting to the prefrontal cortex.

The difficulty of relating the clinical results of a blind operation, in which partial or selective cuts are attempted, to actual topological lesions has been clearly shown in the fine neuroanatomical studies of Meyer and his collaborators (Meyer & Beck, 1945; Meyer & McLardy, 1947, 1948, 1949; Meyer, McLardy & Beck, 1948). The brains of 95 patients dying after leucotomy have now been examined. Meyer & McLardy (1949) state: "The variability of the leucotomy cuts, which was first demonstrated in 1945 . . . is still an impressive finding in cases operated upon in 1946 and 1947." In fact, the surface markings on the scalp bear little constant relation to brain areas beneath. From detailed analysis of the lesions found in their material, and by correlation with the personality changes following the operation, Meyer and his collaborators have not been able to relate lesions in any one cortical area to specific effects upon personality, although there was some evidence that the orbital sector is more important than any other. They were able to show, however, that personality changes persist after bilateral lesions long after the process of active repair is completed. The degree of personality change would appear to be related to the extent to which the thalamo-frontal projection fibres are severed, rather than to severance of any specific sector of these fibres. It is of interest that posterior cuts, involving the cingular, posterior orbital and pre-motor regions—areas concerned with autonomic functions—have undesirable clinical effects, which suggests that a disturbance in the autonomic integration plays little part in the mechanism of improvement. These studies suggest a quantitative relationship between amount of prefrontal cortex isolated, personality change and clinical improvement (Frankl & Mayer-Gross, 1947). If this relationship is found to be valid, the stereotaxic operation upon the dorso-medial nucleus of the thalamus would receive its rationale in cases in which maximal interruption of thalamo-prefrontal fibres is indicated, although the obvious difficulties and dangers inherent in the technique will probably preclude its extensive use.

Turning now from the modifications of the actual operative technique to the general problems of the operation as treatment, we find much the same attitudes towards this, as towards insulin therapy. The operation in itself is almost the least part of the treatment; a prolonged course of re-education is necessary. Mayer-Gross (1948) recommends prolonged convalescence in hospital and warns that where no facilities for re-education of the patient exist, no operation should be performed. Others recommend persistent pressure and urging of the patient to re-adapt, with punishments if he fails to do so.

### 3. Psychological Evidence

Evidence regarding the immediate psychological effects of these treatments is of course meagre, since the patients retain, for the most part, a total amnesia for the experience of the shock. This applies particularly to convulsion therapy and leucotomy. It has been postulated from the

point of view of psychodynamics that "shock" techniques constitute such a threat to the ego's existence that it is freed from guilt by an act of atonement, and thereby strengthened. Against this must be placed the evidence that measures designed to reduce anxiety and awareness to a minimum, or to abolish them altogether, e.g., by pentothal anaesthesia and barbiturate sedation, have no known effect upon the therapeutic efficacy. In this connexion Sands notes that among 50 cases of attempted suicide he had seen, it was noticeable that while many neurotic and psychopathic patients improved following their attempts, the patients with psychotic depression remained suicidal risks as much as before. "Atonement had not been achieved whether consciousness was lost or not, yet in convulsion therapy it is the psychotic depressions who gain while the depressed neurotics and psychopaths show indifferent results." (Unpublished paper: see p. 41, section 5.)

The psychological phenomena of insulin coma parallel the progressive depression of metabolic functions down the neuraxis, with depression of each level resulting in release and overactivity of each immediately lower level—a dissolution of the hierarchical control in Hughlings Jackson's sense. This, in psychological terms, means regression. The progressive disintegration from psychological to motor, to reflex and to autonomic levels of functional organization is seen in reverse during the recovery from coma, and it is when the highest levels still show some depression of function that the patient shows the euphoric, "drunken" behaviour which enables the therapist to achieve contact with him.

#### *a. Effect on Intellectual Functions*

There can be no doubt that all the physical methods of treatment under review produce some alteration in intellectual capacity, although in varying degree. The maximal effect on memory functions is probably produced by convulsions, with insulin comas and leucotomy producing only slight changes. In a few cases, Brody (1944) found measurable defects eighteen months after conclusion of electroconvulsion therapy (ECT). Loss of retentive memory immediately following, and throughout the course of ECT, with recovery within a few weeks after conclusion, can be found in most cases. The current attempts to reduce these memory changes to a minimum reflect the view that they are not significant in the therapeutic mechanism. In the case of ECT, at least, the intellectual changes which, besides memory defects, include dullness, lack of attention to personal habits, and apathy (Salzman quoted by Wilcox, 1947) are regarded as complications of the treatment, not intrinsic to the recovery mechanism. They are greater in the elderly and in the arteriosclerotic. Similar observations have been made both upon insulin-treated patients and upon those who have had prefrontal leucotomy. The confusional state which immediately follows the application of all these treatments is often of the greatest duration following leucotomy, but is probably proportional to the degree of frontal damage, being greater where complete section of white matter has been attempted (Dax *et al.* 1948). The typical expressions describing the symptomatology have been summarized by these workers: "Patients tend to be emotionally shallow, easily influenced in mood and act, lacking in reticence, outspoken throughout,

rude and tactless; introspection is impossible; they lack initiative; egocentric and irritable; have defective foresight and live in the present." From this state, which describes the frontal lobe syndrome familiar after head injury, there is gradual improvement. Reitman (1946, 1948) considers that the partial lower cuts introduced by Dax & Radley-Smith (1946), which tend to isolate the orbital cortex maximally, produce changes—consequent upon the brain damage in these areas—which are most beneficial for those patients with introversion, lack of initiative and shallowness of affect. This view is contrary to that held by Frankl & Mayer-Gross (1947) and is not substantiated as yet by the neuroanatomical studies of Meyer and his collaborators already cited. In their view the resulting mental changes depend upon the amount of prefrontal cortex isolated, rather than upon the selective isolation of special areas. On the basis of this theory, Frankl & Mayer-Gross state:

The surgeon will be asked to produce enough frontal symptoms to combat the symptoms of psychosis—enough euphoria against distress and depression; enough extraversion and distractibility against introspection and withdrawal; enough indifference and freedom from care and worry against obsessions, delusions and fear.

#### *b. Late Personality Changes*

While the immediate after-effect of all three treatments is to produce confusion and some intellectual changes of the type which follows brain injury, it is believed that after a short period the majority of patients treated with insulin or ECT completely recover from these effects. Standard tests of intellectual function, weeks or months after leucotomy, also fail to reveal persisting defects. Yet there can be no doubt that, especially after leucotomy, a fundamental although subtle change has occurred. This can be described only in the emotional field. Brody (1947) found that while his patients showed no impairment on being tested with a battery of standard tests of mental ability given before and six weeks, four months, one and two years after operation, yet there were among them many patients whose spontaneous intellectual activity did not, from observation, reach the level and quality proved, by the tests, to be within their capacity. Brody suggests that the test situation evoked some drive not ordinarily operative after leucotomy. This observation is substantiated by the common finding that ideas and delusions, held with great emotion before the operation, are still present after it but "stripped of emotion". Freeman & Watts (1942), Hutton (1947), Reitman (1947a), and Hutton & Bassett (1948) have described these emotional changes in detail. There is an indifference to criticism, to their own feelings and bodily functions, and to the feelings of others. Consequently there is less reserve and shyness. While still intellectually aware of moral and ethical principles, and unlikely to transgress them, such principles are held objectively. There is less "uplift, altruism, creative spirit, soul or whatever else one would like to call it" (Freeman & Watts, 1948). These subtle but profound alterations in the affective life of the leucotomized patient do not occur in those subjected to convulsion therapy, nor are they obvious in those treated by insulin, although here the problem is beset with the great difficulty that the schizophrenic, in whom alone insulin comas are induced, is already affectively dulled as a result of psychosis.

#### 4. Physiological Evidence

Many investigators (Gellhorn, 1943; Himwich, 1944; Meduna, 1945) have been impressed by the similar physiological effects of the various shock treatments. Similarities are seen in alteration of some blood constituents, of cerebral oxidation mechanisms and in the effects upon the autonomic nervous system. Theory regarding the significant common factor is divided between cerebral anoxia (Himwich, 1944; Meduna, 1945) and alterations in the excitability of the autonomic nervous system (Gellhorn, 1943). It is emphasized that the bodily response to the therapeutic agent, rather than the agent itself, is the significant factor. These responses are understood as adjusting or homeostatic mechanisms called out to preserve the internal environment of the body. The changes which occur immediately in the therapeutic convulsion—hyperglycaemia, fall in  $\text{CO}_2$ , increase in lactic acid, acid shift in blood pH, stimulation of the sympathetic-adrenalin system—are seen in the second stage of insulin shock therapy. Meduna (1945) relates the similarity of the blood changes in the shock therapies and in diabetes to the fact that certain schizophrenics behave like diabetics in their response to the insulin tolerance test, and suggests that the diabetic-like behaviour of the schizophrenic patient in this respect is but an unsuccessful defence against the disease. He further suggests that all treatments, to be successful, must interfere with the enzyme systems of carbohydrate metabolism.

The view that cerebral anoxia is the operative factor in insulin and convulsion therapies is not, however, universally held. While anoxia is certainly profound in hypoglycaemia, Gellhorn (1943) brings evidence against its importance in ECT. Clearly the brain suffers anoxia during the convulsion because of the respiratory embarrassment, but from direct observation of the vessels vasoconstriction has not been reported. The decrease in arterial oxygen tension found by Himwich (1944) during the convulsion does not occur in curarized animals maintained by artificial respiration (Libet, Fazekas & Himwich, 1940). More important from the point of theory is that techniques aimed at reducing apnoea to a minimum do not diminish the therapeutic efficacy (Wilcox, 1948). The outstanding common factor present in the two treatments is considered by Gellhorn (1943) to be the increased excitability of the autonomic system, particularly the sympathetic-adrenalin system. Hyporeactivity of the organism's defences, which are provided by the sympathetic-adrenalin system and relative preponderance of the vago-insulin system, is, perhaps, one of the most important substantiated physiological findings among schizophrenics. In insulin hypoglycaemia there is progressive depression of function in the central nervous system but progressive excitation of activity of the autonomic system, with preponderance of the sympathetic-adrenalin activity. Moreover, it is believed that only those patients who produce an increased amount of adrenalin during treatment respond satisfactorily. In electrical convulsions a profound excitation of the central nervous system occurs, as well as stimulation of the autonomic system, which again affects the sympathetic more than the parasympathetic centres. Gellhorn (1943) has found evidence that the hypothalamus shows an increased excitability which may continue for hours after metrazol convulsions in animals.

In prefrontal leucotomy we are clearly dealing with a

different situation. The general effects on the nervous system, apparent in the other treatments, are not present, but some changes in autonomic activity have been described (Reitman, 1947b; Rinkel *et al.* 1947), although the findings are not consistent. After an initial hyperreactivity of the autonomic system in the weeks following operation a more stable and unresponsive homeostasis is later reached, according to Reitman. Rinkel and his colleagues, however, report that the autonomic system becomes more responsive to external stimuli after leucotomy. Stimulation of the carotid sinus produced bradycardia, slowing of EEG potentials, loss of consciousness and tonic-clonic convulsion in 88 per cent of patients operated upon. Similar sensitivity was found among patients who had received ECT. Clearly the changes in autonomic functions require further investigation in leucotomized patients. At present the emphasis lies on the amount and site of the isolated prefrontal cortex, which are regarded as the significant therapeutic factors.

The importance attached to the change seen in the autonomic system has again directed attention towards the diencephalon. Delay (1946), Murphy & Gellhorn (1945b) and Wilcox (1948) subscribe to the theory that the site of action of the therapeutic convulsion lies in this area. It is improbable, but not excluded, that excitation of peripheral autonomic pathways plays any part. Murphy & Gellhorn (1945a) provide good evidence of the effects which excitation of hypothalamic centres have on cortical functions independently of the peripheral autonomic pathways. The direct route is from the sympathetic centres in the hypothalamus via the dorsomedial thalamic nucleus to the cortex. Widespread excitatory effects on the spontaneous electrical activity of the whole cortex, as shown by the EEG, and facilitation of motor, and probably sensory, functions follow stimulation of sympathetic focal points in the hypothalamus. Studies of the changes in cortical function in these treatments, as shown by the EEG, have been frequently made. The depression of cortical activity during hypoglycaemia and during the stage of clinical exhaustion after ECT is shown by the presence of generalized slow waves in the EEG. In insulin hypoglycaemia the changes are progressively towards slowing, but during the electrical convulsion the EEG reflects the maximal excitation of cortical neurones. Slow activity in the prefrontal areas, rostral to the leucotomy cut, is seen for some weeks after the operation. In each method—hypoglycaemia, convulsions and leucotomy—the amount of disturbance in the EEG following the treatment is proportional to the persistent cortical dysfunction, and probably reflects the degree to which the intellectual functions are impaired. Unfortunately for theory, the changes in the EEG cannot be related to the process of recovery from the psychosis.

### 5. Clinical Approach

The immense literature makes it abundantly clear that the selection of the appropriate treatment and the decision as to whether any given patient is likely to respond are dependent upon factors other than the nature of the mental disorder present, or the nature of the treatment proposed. While it is still generally held that hypoglycaemic coma is the treatment for schizophrenia and, more firmly, that ECT is specific for some depressions (Sands, in a paper read at the Royal College of Physicians International

Congress, London, September, 1947; Sargant & Slater, 1948), the recent literature suggests that leucotomy is beneficial to both types of patient. Indeed, the indications for success by physical methods would appear to cut across diagnostic categories as we at present know them (Fernandes & Polonio, 1946). Symptoms rather than diagnostic syndromes may well determine the choice of a particular treatment. This is emphasized by the advocacy of ECT for the mental symptoms of organic disorders such as general paralysis of the insane after the appropriate specific treatment has been given.

The expectation of a favourable response to any method is, in the last resort, a variable dependent upon the expectation of recovery if no treatment were given. This, of course, is not to deny the efficacy of physical methods, which the writer considers to be beyond question. At the present time the symptoms of depression with agitation, diminished psychomotor activity, mild confusion and catatonic stupor or excitement, lead to the administration of ECT. Insulin comas are usually given to patients suffering from thought disorder of schizophrenic type, in the absence of the above symptoms, or after failure of ECT to produce a remission and provided that for other reasons, such as the duration of illness, a remission can still be expected. Leucotomy is advised for those patients whose main incapacity lies in chronic obsessional tension or in chronic paranoid pre-occupations and delusions. Usually, however, leucotomy is carried out after the failure of other methods to produce a remission. Nevertheless, all are agreed that in established hebephrenia, where the prognosis without treatment is well-nigh hopeless, none of the physical methods is of any avail. Mayer-Gross (1948) says in this connexion: "... hebephrenics showing only lack of initiative, affective blunting and facetiousness are themselves too akin to the frontal syndrome to permit any improvement after operation."

From the formulation of a patient's total situation—the process which constitutes psychiatric diagnosis—the physician is confronted by three main avenues of therapeutic approach. In the first, the environmental stresses are reviewed and every effort made to remove, or at least reduce to a minimum, their noxious effects. In many instances these are of the greatest significance, but it may not be possible to alter them. In the second approach, the physician reviews the effect which environmental stresses, past and present, have had upon the patient and considers to what extent such effects can be changed. This constitutes the field of psychotherapy. In the third and last approach, the constitution of the patient, i.e. his machinery for adaptation, is considered. It is here that the physical treatments probably act. The clearest exposition of the rationale of the constitutional approach is provided by Sargant & Slater (1948).

Causation in psychiatric disorder—as indeed in the whole of medicine if symptoms are considered—is always multiple. A primary cause may be present, as for example in general paralysis of the insane or in Huntington's chorea and in some cases of simple schizophrenia where the hereditary factors are prepotent. In the majority of functional psychoses, a primary cause is usually not detectable; nevertheless, it is necessary to try to decide which factors constitute predisposing causes, which precipitating causes. The latter are not necessarily psychogenic, nor physiogenic,

in the exogenous sense. The loss of a love-object or an attack of influenza may precipitate a depression, but age is the most important precipitant of involutional melancholia. The physical treatments probably affect the organism's situation by modifying the organism's constitution. It is, therefore, for those conditions in which constitutional weaknesses are etiologically prepotent that such methods are found of greatest value. The assessment of the patient's constitutional strengths and weaknesses is one of the hardest tasks of the psychiatrist, whose efforts are bent on weighing up the multiple factors, genetic, physiogenic, psychogenic, intrinsic and extrinsic, which the history reveals. In the broadest and simplest terms, the constitution can be regarded as the organism's machinery for dynamic adaptation to the world. Predetermined in part by genetic factors, its manifestations are nevertheless always subject to change from bodily disease, trauma, or to the operation of hitherto unexpressed genetic deficiencies liberated by, say, the factor of age. Little enough is known about this machinery. Age, physique, intelligence, temperament—these are qualities of discernible significance.

The central nervous system maintains our immediate relationship with the external environment, and the autonomic nervous system safeguards the all-important stability of the *milieu intérieur*. The evidence relating changes in autonomic function to the treatments under consideration has already been reviewed. Clinical observation of the patients adds further data. Increase in weight occurs during insulin therapy, after ECT and after leucotomy. Appetite is splendid, sleep is sound, and there is "a greater freedom in demeanour and bearing" (Frankl & Mayer-Gross, 1947). Sargant & Slater (1948) advise that the patient receiving insulin comas should continue until his physique has returned to normal. "Mental improvement and physical improvement usually go side by side . . . If the patient regains his normal weight and physical state, and retains his mental symptoms unaltered, it is a bad sign, and it is usually not worth proceeding further." During the hour or two after recovery from insulin coma the patient's skin is flushed and glowing, and he is warmer and friendlier in his manner to the doctor and nurses. The change in the affective attitude is very prominent, lasts progressively longer after each coma as the treatment proceeds, and is a characteristic of those patients who recover.

## 6. General Conclusions

The main problem with which the treatment of the functional psychoses presents us is not so much to alter mood, or to eradicate thought disorder, but to offset the secondary psychological effects which result from prolonged illness. The schizophrenic, for example, is faced with progressive social incapacity, loss of volition, and decreased affective resilience and responsiveness. The longer the patient has been removed from active participation in the dynamic life of society and family, the less likely it becomes that he will ever regain his social capacity. The greater the duration of his illness, the more profound the isolation of the patient from normal contact with his fellows, the more serious the resultant "scarring" of the personality will be. In a sense, therefore, every psychosis calls for

emergency measures to reinstate the patient in a normal relationship with his environment before some critical time, after which the chance of doing so greatly decreases. In the case of schizophrenia, we know that this remains good in the first six months, becomes poorer up to two years and thereafter is slight. No known physical or psychological therapeutic technique can add positive qualities to a personality which did not possess them before the illness began. Indeed, prefrontal leucotomy usually deprives the patient of certain qualities with which, and perhaps because of which, he has failed to adapt. These losses may be permanent, but of this we are uncertain. The problem is similar to that often encountered after severe cerebral trauma to the frontal lobes. The psychological evidence shows no comparable losses after ECT and insulin comas. Follow-up studies of patients treated indicate that insulin and ECT do not alter the probability of second or further attacks occurring, but there can be no doubt that the duration of illness is considerably reduced by these treatments. Moreover it has been repeatedly emphasized that the quality of remission is better than if no physical method had been used. The results are much better if a full programme of re-education, psychotherapy and social activities is carried out during and after treatment. This has received increasing emphasis from those engaged in treating large numbers of patients. The remission rate from the insulin treatment of schizophrenia was increased from 46 % to 79 % when these principles were adopted (Bond & Rivers, 1942). Mayer-Gross regards re-education as essential after leucotomy, and states that the operation should not be performed unless it can be assured.

At the present time, in the absence of real evidence of specific effects from these treatments, it is reasonable to assume that by their use the patient's constitution is temporarily altered in such a way as to render him open to a variety of re-educative processes. The importance to be placed upon these is greatest in the case of insulin hypoglycaemia and prefrontal leucotomy, less in the case of ECT. This is understandable since the patients who respond to ECT are those with the stronger, better balanced constitutions. In them the balance of the processes determining the quality of the affective tone has been temporarily disturbed. The constitution, given the necessary stimulus, re-equilibrates rapidly and shows once more the resilience which was previously observable in the patient's personality.

The precise manner in which the constitution is altered by these methods remains an intriguing but obscure problem. The strictly psychodynamic theories do not receive any support from the technical data. It is increasingly probable that the treatments act immediately by modification of physiological activities, but these in turn promote an altered situation in which psychological factors become of the greatest significance. Thus, prefrontal leucotomy, by producing the frontal lobe syndrome, creates a total psychological integration which is less complex, and re-introduces a state of plasticity of adaptation in which the patient is open to re-education. Insulin hypoglycaemia and ECT both produce unconsciousness and a variable period of mental confusion after the treatments in which, again, the patient's emotionally determined attitudes are altered. But this is not all. In hypoglycaemia it is the comas, and in ECT the actual convulsions, that are necessary to thera-

peutic efficacy. The arousal, stimulation and exercise of homeostatic defence mechanisms mediated by the sympathetic-adrenalin system may be, as Gellhorn (1943) has suggested, of therapeutic significance. The mobili-

zation of the somatic mechanisms of emotional expression may certainly be important in the treatment of those conditions in which affective unresponsiveness to the environment is a main feature.

The interaction of body and mind is a two-way process and under this heading must therefore be considered (i) the influence of somatic factors on the mental state and (ii) the influence of the mental state on bodily functions. Normally we are dealing with an interaction in which both are intimately interwoven, the body and mind working together as a whole.

### 1. Psychosomatic Interaction

The anatomical structures which may be involved in psychosomatic dysfunction include, on the motor side, the numerous ramifications of the autonomic and endocrine systems, which are controlled through the hypothalamus: on the sensory side are the visceral and somatic afferents and the chemoreceptor mechanisms concerned with the maintenance of homeostasis and with the different forms of appetite and drive. The integration of these mechanisms in the higher centres of the brain is as yet little understood; but it is clear that there is a continuous interaction between the somatic and higher functions and that this interaction is of such a kind that a dysfunction at any one level can give rise to a vicious circle involving the whole system. Thus, anxiety can give rise to symptoms which can in turn become a focus for further anxiety.

A physiological or metabolic stress may contribute towards a mental breakdown, the form of which will depend on predisposing constitutional factors, such as mental instability associated with an emotionally labile or a schizoid

personality. Factors such as septic foci or acute infections may aggravate the picture, while psychological frustrations and traumata deriving from unsatisfactory personal or sociological relationships may again be important as contributory or precipitating causes. The factors which appear to be significant in the causation of psychosomatic dysfunction may be considered under such headings as (i) genetic, (ii) constitutional, (iii) infective, (iv) endocrine, (v) metabolic and (vi) psychological. Such categories are not mutually exclusive, but may serve as a convenient method of approach. In many patients the mental and physical factors are so closely linked up that it is impossible to say which is cause and which is effect. Instead of the old question of whether a condition is psychogenic or physiogenic, it is generally more profitable to examine how much significance can be attached to the various contributory factors of each kind.

The view of multiple causality adopted in the present article has been expressed by Cobb (1947): "One must take a pluralistic point of view toward etiology and realise that many factors combine to bring about the concatenation of events which precipitates a clinical syndrome."

### 2. The Influence of Constitutional Factors

The effect of any somatic factor on the mental state depends partly on the physiological mechanisms through which it acts and partly on the constitutional make-up and personality of the individual concerned. The importance of constitutional factors in determining the mental reaction to a stimulus was recognized by Pavlov (1927), who observed that "the same influence may produce a profound disturbance in some individuals and show no trace of effect in others, according to the power of resistance of the nervous system in each case." He noted in his experiments on dogs that different animals often reacted to a stress in opposite ways, some becoming bold and over-active, while others became "cowardly" and inhibited.

This individual variation in the response to a stress is shown very clearly in more recent work on the production of experimental neurosis in human subjects by deprivation of vitamin B<sub>1</sub> (Williams & Mason, 1941; Jolliffe *et al.* 1939). Volunteers living on a diet deficient in vitamin B<sub>1</sub> were generally observed to become apathetic, irritable and quarrelsome, with loss of efficiency, as indicated by inattentiveness to detail and lack of manual dexterity in their work. Objective signs of deficiency were shown by ergographic and electrocardiographic tests. The experimental neurosis presented different forms in different individuals, depending on their previous personality. Some became markedly depressed, others hypochondriacal. In some, the chief symptoms were anorexia, lassitude and fatigue, the picture resembling that of anorexia nervosa, while others developed the breathlessness on exertion, giddiness, palpitations and precordial pain, which are seen characteristically in neurocirculatory asthenia, or "effort syndrome". The severity of the symptoms was augmented by physical activity and by cold weather. Recovery was rapid and complete when vitamin B<sub>1</sub> was given, with or without the knowledge of the subject. In some cases the recovery was marked by a subjective experience of unusual well-being associated with unusual stamina and enterprise, the subjects becoming more alert and attentive.

A similar individual variation in the reaction to a metabolic stress was observed in the starving population of Germany after the war. Of the patients referred to the clinics on account of starvation oedema, some showed anxiety and some were depressed, some became over-active, while others showed a schizoid withdrawal. Reactions of the "effort syndrome" type, with lassitude, breathlessness, giddiness and fatigue, were common. The condition was not remedied by administering vitamin B<sub>1</sub>, but it cleared up rapidly when a full adequate diet was given.

The importance of the previous personality in determining the manifestations of a psychosis is well known in the case of general paresis, which can take strikingly different forms. It is illustrated again in the recent work on the toxic psychoses produced by treatment with the antimalarial drug atabrine (mepacrine). About 0.1 per cent of all cases treated developed psychoses. In about a half of these the psychosis showed manic or depressive features, the manic reaction predominating, while in a quarter the psychosis was schizophrenic in type, the patients showing the usual catatonic, paranoid or hebephrenic features (Grieber, 1947; Perk, 1947).

### 3. Somatic Aspects of Personality

Recent work has confirmed to a considerable extent the early views of Kretschmer on the relationship of body-build and personality (see Rees, 1947). Physical constitution is determined largely by genetic factors, which may produce their effect to some extent through the endocrine mechanisms. These again bear a close relationship to personality, as illustrated by the well-known personality changes associated with dysfunction of the hypophysis, thyroid, adrenals, testes and ovaries (Reiss, 1944).

The genetic factors are mediated by the genes, which are generally believed to govern the enzymic make-up of the tissues, controlling the tissue metabolism and therefore the production of metabolites. Factors such as the rhesus agglutinin can be related to the action of particular genes and it is reasonable to believe that they play an important part in determining the individual variations in metabolic function which are found in almost any biochemical investigation of normal as well as of psychotic subjects. A few cases are known in which biochemical factors bear a relationship to personality, as in the tendency to hyperchlorhydria in the group of individuals subject to peptic ulcer; these constitute a fairly distinctive personality-type characterized by a worrying temperament and excess of drive.

The relationship of drive and instinct to somatic factors has recently been reviewed by Kubie (1948), who concludes: "There are no absolute distinctions between instincts and drives. The nucleus of each is a neuronal pattern which is partly inherited and partly acquired and modified through learning and conditioning." "All instincts consist of (a) the direct or indirect expression of biochemical body processes through (b) inherited yet modifiable networks of synaptic patterns which (c) are moulded in turn by superimposed, compulsive and phobic mechanisms." This is not incompatible with Freud's definition of instinct as "the measure of the demand for work imposed upon the mind in consequence of its connexion with the body."

Electroencephalographic studies have shown that the electrical rhythms of the cortex are almost as characteristic

of the individual as finger-prints, and particular traits such as specific forms of dysrhythmia often run in families. The alpha rhythm is easily blocked by fear, so that little is seen in tense and anxious subjects. Golla, Hutton & Walter (1943) used the blocking of the alpha rhythm as an indication of the type of mental imagery habitually used by the individual, and Hill & Watterson (1942) were able to identify two theta rhythms (one at 6 cycles/sec. in the parietal and another at 4 cycles/sec. in the temporal region) which could be correlated with a tendency to aggressive behaviour. Theta rhythm of this kind is common in young children but abnormal in adults: its appearance in aggressive psychopaths suggests a developmental failure in the maturation of the adult structure of the brain (Hill, *in press*).

### 4. Physiological Changes in Emotion

Emotion is associated with physiological changes which may affect the blood pressure, pulse rate, glandular secretions, blood sugar, and many other physiological functions, as well as the electroencephalogram (EEG). Cannon and his collaborators (*cf.* Cannon, 1915) built up a picture of physiological and biochemical changes in anger, fear, rage and pain, all mediated by the sympathetico-adrenal system and designed for the preservation of the individual in fight or flight; but in actual fact it is found that individuals differ considerably in their reactions to emotion and the responses do not conform to a uniform pattern of this kind. During air raids, for example, it was evident that while some subjects turned white when the bombs came down, there were others who flushed red in the face; while some became tense and hyperactive, there were others who felt faint; in some the discharge was mainly through the sympathetic, but in others through the parasympathetic division (Richter, 1945). If this variability is true of the physiological changes, it is likely to be equally true of the biochemical. The teleological views on the utility in fight and flight of these changes are unconvincing. The physiological changes may be regarded as attempts at achieving a readjustment of the individual to a new relationship with his environment. Sometimes they are beneficial but sometimes they are not.

#### *a. Skin Reactions*

Besides the changes in the visceral organs, emotional excitement is accompanied by demonstrable changes in the blood capillaries, hair follicles and sweat glands of the skin. Of these the first two are supplied by adrenergic nerve fibres and are susceptible to the action of adrenaline, while the sweat glands are supplied by sympathetic nerve fibres which are cholinergic. The changes in the sweat glands in emotion are mainly responsible for the "psycho-galvanic reflex". There is also evidence of nerve fibres in the skin which can release a histamine-like substance and which have therefore been described as histaminergic.

The effects of emotional excitement on the skin are seen in reactions such as pallor, flushing, erection of the hair and angioneurotic oedema, the last being often localized in its distribution. This is also seen in many of the pathological skin reactions often described as psychosomatic. Cases have been described in which erythema and weals have been produced by hypnotic suggestion, and there are a few recorded cases of localized skin reactions produced

during abreaction (Harris, 1948). Moody (1946) has reported a case of some interest (fig. 1) in which rope-marks appeared on the arms during the abreaction of a patient

FIG. 1. PSYCHOSOMATIC SKIN MANIFESTATION

By kind permission of Dr. Moody and of the Editor of the *Lancet*

Photograph of right forearm with indentations and oedematous edges resembling rope marks, which appeared during abreaction

who re-lived an incident in which his forearms had been tightly bound with rope. The evidence indicates that the brain is able to retain the "memory" of a comparatively complex cutaneous motor pattern, which may be released at a later date by invoking an associated emotionally-charged complex.

#### *b. Changes in the Brain in Emotion*

The importance of the interactions between the cerebral cortex and the hypothalamus in emotion has been appreciated since the early investigations of Head (cf. Head *et al.* 1930). Recent work has extended our knowledge of the changes in the electrical rhythms of the cortex induced by emotion. Generally there is a reduction in the alpha wave frequency and an increase in faster frequencies, but the changes are not consistent (Hill, in press). In some cases there appears a stable rhythm at 20 cycles/sec. in the frontal and parietal lobes (Cohn, 1946).

Information about the metabolic changes in the brain has been obtained from animal experiments in which the biochemical changes in the brain are fixed by rapid freezing with liquid air. By this method it was found that the lactic acid content of the rat brain is significantly lower during sleep than in the normal waking state (Richter & Dawson, 1948a). In emotional excitement the lactic acid content of the brain is considerably higher than normal and over 300 per cent above the mean level for sleeping animals. Associated changes have also been observed in the phosphate esters and in other metabolites of the brain in emotion (Richter, in press).

#### 5. Reaction to a Metabolic Stress

The effect of a metabolic stress on the mental state depends on whether the stress is acute, as in a sudden

hypoglycaemic attack, or chronic, as in a vitamin deficiency extending over a prolonged period. In acute metabolic stress we are dealing with a direct interference with cerebral function; in chronic stress it may be hard to distinguish between the direct effect and the secondary reactions due to the repeated conflicts and frustrations which may be occasioned by the disability in everyday life. Here the form of the reaction is likely to depend to a much greater extent on the constitution, environment and personality-trends of the individual.

##### *a. Acute Metabolic Stress*

The reaction to a sudden acute metabolic stress causing a general impairment of cerebral function is frequently of the type described by Hughlings Jackson as "dissolution at the highest level". This reaction is non-specific in that it may be produced by a wide variety of conditions: these include anoxia, hypoglycaemia and various toxæmias. It may also be caused by a number of toxic substances such as carbon monoxide and many narcotic drugs which interfere with the metabolism of the brain. The reaction consists of a primary impairment of the highest cerebral functions, with loss of judgement and insight, impairment of intellectual ability and loss of emotional control, leading, through progressive stages of increasing confusion, to delirium and final unconsciousness. That the highest cerebral functions should be the first to suffer is understandable in view of the high metabolic requirements of the cerebral cortex. Along with impairment of metabolism goes a slowing of the electrical activity of the cortex and a lowering of the electrical potentials, leading finally to a cessation of electrical activity when unconsciousness has been reached and the cortex is completely out of action.

##### *b. Anoxia*

The mental changes in anoxia have recently assumed some importance in connexion with high-altitude flying. Emotional control and judgement are impaired by relatively mild degrees of anoxia; and as military flying is now often conducted at altitudes of up to 40,000 feet anoxia may occur, even when pure oxygen is being inhaled. The effects of anoxia on cerebral function, as indicated by the reduced performance of decoding tests and by impairment of vision, can be correlated with the changes in the EEG (Proger & Dekaneas, 1946). As the electrical activity is sensitive to biochemical changes in the cerebral cortex, it can thus serve as an indicator of the metabolic activity.

Impairment of visual discrimination is often an early sign of cortical dysfunction in anoxia. Engel *et al.* (1944) observed the occurrence of migrainous attacks accompanied by hemianopia or scotoma under high-flying conditions and they were able to show that the position of a scotoma could be correlated with the appearance of patches of slow delta rhythm, localized accurately to the corresponding visual-projection area of the cortex.

Even with an acute metabolic stress such as anoxia there is still a considerable variation in the individual response, which depends, amongst other things, on the basal metabolic rate; this is easily shown by animal experiments, in which the resistance to anoxia can be greatly increased by thyroidectomy. The effects of anoxia in producing "pilot error" are augmented by emotional over-breathing at high altitudes when expecting combat (Rushmer, 1944). Hypo-

glycaemia also exerts an aggravating influence: oxygen and glucose act in a similar manner on the brain potentials, so that the effects of anoxia can be offset by raising the blood glucose level. This has found practical application in the administration of glucose before high-altitude flying.

### *c. Prolonged Metabolic Stress*

Among the commonest reactions to a chronic metabolic stress are anxiety and depression, which may result from almost any physical or metabolic inadequacy to which the individual is unable to adjust. Anxiety and depression are not necessarily pathological; they may even be regarded as serving a useful purpose in so far as they help in adapting the behaviour of the individual to a physical disability because of which he is unable to cope with the demands of the environment. This was seen during the war in many cases of post-infective neurosis, in which the general debility after an acute influenzal or other infection interfered with the demands of military training and led to the development of an anxiety state.

### *d. Neurocirculatory Asthenia*

Among the reactions of patients suffering from chronic metabolic disorders is that described as "neurocirculatory asthenia" or "effort syndrome", since low tolerance of effort is often the presenting symptom. The symptoms are mainly referable to autonomic dysfunction and include breathlessness, palpitations, dizziness, chest discomfort and fatigue; in addition there may be anxiety, sweating, headache, trembling, and gastrointestinal disturbances (Jones & Lewis, 1941; Cobb, 1947). The syndrome has been observed in starvation, in vitamin deficiency and as a reaction to repeated hypoglycaemic attacks (Greene, 1944). It may be precipitated by an acute infection or by hyperventilation tetany. Jones & Scarisbrick (1942) have described the same syndrome in patients suffering from a type of metabolic disorder characterized by an abnormal rise in the blood lactate and a high oxygen requirement in the performance of physical work. Here again environmental and constitutional factors all play a part. The influence of genetic factors in determining the form of the reaction is indicated by the high incidence of neurocirculatory asthenia in the near blood relations of those suffering from the condition.

## 6. Somatic Factors in Epilepsy

Convulsions may occur as an unspecific reaction to a great variety of toxic substances which exert an irritant action on the brain.

### *a. Epileptic Seizures*

The metabolic nature of the disturbance in idiopathic epilepsy and the epileptic psychoses is suggested by the well-known effects of acidosis and sedation in preventing seizures and of hydration, alkalosis, hypoglycaemia and stimulation in precipitating them. The frequent association of epilepsy with abnormalities in the electrical rhythms of the cortex again points to a metabolic dysfunction; but dysrhythmia is often found in the normal relatives of epileptics, so that something more than dysrhythmia alone is needed to account for the occurrence of seizures. The biochemical factors determining the irritability of the brain

are not yet known; but it is suggestive that Pope (1948) and his collaborators have reported an abnormally high cholinesterase activity in epileptogenic zones of human subjects and monkeys.

The metabolic nature of the disturbance in *petit mal* is suggested by the action of glutamic acid, which is reported effective in some cases in reducing the incidence of the attacks (Price, Waelsch & Putnam, 1943; Waelsch & Price, 1944). Waelsch has suggested that glutamic acid may act by providing an essential unit needed for protein synthesis, but its action in *petit mal* epilepsy and in improving the performance of intelligence tests is not yet understood (Albert & Warden, 1944; Zimmerman & Ross, 1944).

Electroshock treatment and convulsant drugs cause a rapid breakdown of high-energy phosphate esters in the brain, leading to the utilization of carbohydrate and a liberation of lactic acid and inorganic phosphate (Richter, *in press*). Associated with these changes is a rapid liberation of ammonia, showing a direct action of shock treatment on the nitrogen metabolism of the brain (Richter & Dawson, 1948b). Ammonia is itself a cerebral irritant and it has been suggested that the ammonia liberated through stimulation may play a part in the initiation of convulsions.

### *b. Psychical Seizures*

Psychical seizures may take the form of hallucinations, "forced thinking", or ictal automatism. Any of these forms may end in generalized convulsions and may thus be said to become motor, although at the outset they are purely psychical phenomena (Penfield, 1947). Elaborate dream-like hallucinations are fairly common manifestations of psychical seizures and here the attacks can often be related to a focal electrical discharge in the cortex of one temporal lobe. The experience may be entirely visual, such as a vivid scene from the past, but there is usually some doubling of consciousness, with a realization that the occurrence is unreal. Penfield (1947) has described a case of a girl, subject to psychical seizures, in whom different features of her hallucinations could be evoked at will by stimulating precisely localized points of the temporal lobe when her brain was exposed under local anaesthesia. The points remained constant for each particular feature.

Psychical seizures can also take the form of "forced thinking", in which a feeling of compulsion to think certain unusual thoughts is the preliminary to a seizure. Stereotyped behaviour is often associated with a lesion in the frontal lobe and in one case Penfield was able to confirm by means of intracranial electrodes that a seizure was preceded by a unilateral spike-and-wave discharge in one frontal lobe, followed later by a period of flattening or "fatigue" in the EEG. This period, when the frontal lobe was presumably functionally inactive, corresponded to the period of automatism. The observations suggest that the mental confusion and abnormal behaviour of automatism are due to a temporary functional paralysis of a part of the brain (Penfield, 1947).

## 7. Somatic Factors in Schizophrenia

Schizophrenia is seen clinically as a group of psychoses differing widely in mode of onset, course and prognosis. It is difficult to generalize about a group which shows so little appearance of being homogeneous, but there are a

few physiological findings which apply to a high proportion of the patients included in this category. For the most part, these observations can be related to a dysfunction of the autonomic and endocrine mechanisms controlled by the hypothalamus.

It was pointed out some years ago by Pfister (1937) that the somatic changes in the early acute stage of schizophrenia are different from those in the chronic stage. Patients in the acute stage of motor tension and affective excitability are often over-reactive to stimuli, while those who have reached the chronic stage of apathetic disinterest are generally under-reactive to stimuli. It is thus necessary to define the clinical state at the time of examination, and particularly the degree of emotional excitement, as well as the diagnostic category. Failure to realize this has led to many contradictory results and misunderstandings.

The under-reactivity of the chronic schizophrenic observed by Pfister referred to (i) the adjustment of pulse-rate to posture, (ii) adjustment of blood-pressure, (iii) thermal regulation, (iv) the histamine response of the skin, (v) the water excretion after taking fluid, (vi) the blood-sugar response after taking fructose, (vii) the hyperglycaemic response to adrenaline and (viii) the response to insulin. This under-reactivity of the chronic schizophrenic has been confirmed repeatedly, and extended by other investigators to include many other similar functions. Hoskins (1946) mentions (ix) the thermal response to dinitrophenol, (x) the lymphocyte and adrenal response to cold, (xi) the nystagmic reaction to rotation in a revolving chair and (xii) the cardiovascular response to adrenaline. The evidence points to some kind of organic change at a hypothalamic level and also perhaps in the vestibular apparatus.

Evidence of the frequency of endocrine abnormalities in schizophrenia has accumulated since the early work of Mott (1917). Many different types of endocrine changes may be involved and these include dysfunction of the ovaries, testes, thyroid, pancreas, adrenals and hypophysis. The lack of specificity in the observed changes makes it unlikely that any single endocrine abnormality plays a dominant role in the etiology of schizophrenia: it has also been pointed out that schizophrenia is not particularly common

among patients known to be suffering from endocrine disorders. It appears likely that the endocrine changes in schizophrenia are again secondary to a primary disorder affecting the control of the neuro-endocrine system by the brain. If the view of multiple etiology is accepted, there may be cases in which an endocrine imbalance is a contributory or precipitating factor—puerperal schizophrenia may be a case in point.

The dramatic effect of agents such as sodium amylal in occasionally restoring certain schizophrenics for a brief period to near normality, points to a subcortical level as the site of the dominant lesion in these cases. This is also indicated by the prominent symptoms such as emotional incongruity, disorders of consciousness and lack of drive in the clinical picture of schizophrenia. The EEG shows no specific abnormality in the cortical rhythms in schizophrenia, but unspecific abnormalities are more common than in normal controls (Hill, in press).

Gjessing (1939) showed that the phasic changes in the mental state of periodic catatonics are associated with phasic changes in the nitrogen metabolism, and more recent work has extended this to include other metabolic functions. Both the mental and the metabolic changes are influenced by thyroid administration and in some cases by the nitrogen intake in the diet. The evidence is that the mental disturbance is closely linked with a cyclical metabolic disturbance which is presumably controlled at a subcortical level.

The importance of constitutional factors in schizophrenia is indicated by the reduced incidence in subjects of pyknic body-build (Rees, 1947). That the probability of developing schizophrenia rises with increasing closeness of blood-relationship to a schizophrenic emphasizes the importance of the genetic factors. In individual cases there is often evidence that acute infections and psychological trauma are significant as precipitating causes: the schizophrenic reaction has also been observed to follow organic head injury and the administration of toxic drugs. It would appear that somatic factors can play a part in the causation of schizophrenia, and that the hypothesis of multiple etiology agrees best with the facts available at the present time.

  - 4 Problems of child guidance
- References

In considering the history of medicine, we find each period of advance is rendered productive as a result of the fertilizing influence of one or other of the allied sciences. This is particularly true of the development of psychiatry. As general medicine has been reinvigorated by the aid of physics, chemistry and, later, sociology, so too has psychiatry been repeatedly dragged out of the rut by being attached to the strong and younger teams of neurology, psychology and the applied social sciences.

Although not obvious it is nevertheless true that child psychiatry, the youngest offshoot of psychiatry, has been affected by influences which go back for nearly two centuries. It would be historically blind not to admit the early influence of Rousseau and later of Pestalozzi, who, stressing the natural rights of the child and its key position in any society, awakened men's interest in the needs of the child as a creature having special capacities and growth potentials. As paediatrics became a special branch of medicine, clinicians came to realize the particular disorders of children not only in the symptomatic sense, but also in the field of metabolism, and the proneness of the child to certain metabolic nervous disorders produced at the same time an awareness of those other nervous disorders which arose from the child's helplessness and dependence on adults.

### 1. Factors Influencing the Child

Nevertheless, it seems to have taken a long time for paediatricians to realize that children have a mental life of a very special kind. Apart from the recognition of a different degree of intellectual defect, clinicians envisaged mental defect as the manifestation of gross disorders of the brain; in earlier days idiocy, feeble-mindedness and the like were regarded as clinical forms, rather than as grades of inefficiency. The functional view of defectiveness became possible only when Binet and Simon, tackling a purely educational problem thrown upon them by the inadequacy of teachers' class-room estimates, realized that a scale of efficiency was required which would have an objective

validity (Binet & Simon, 1911). As soon as mental tests were developed from their first efforts at analyzing the schoolchild's capacity, it was possible to see defectiveness as part of an imperceptible gradation from amentia to near genius. In fact, the normal frequency curve of distribution enabled other workers to look for the causes of differences within given age-groups. From this, it was only a step to Spearman's theory of two factors and rival hypotheses as to the nature of abilities in the totality of human intellectual output (cf. Spearman, 1927). Here was forged a new instrument of value to the child educationalist and psychiatrist. The significance of these researches to child psychiatry will be referred to again.

With the advance of neurology, another dimension was added to the study of the child mind by the special attention that was given to the study of aphasia and its relation to the apraxias, lefthandedness, mirror-writing and the special symbolism of arithmetic. Orton and his collaborators established the relationship between lefthandedness and stammering, which bore fruit in such scholastic studies as the difficulties of a child backward in reading and writing (Orton, 1937). The child handicapped in this way was later found to be the child struggling to keep up with class demands, which broke his morale and produced divers emotional repercussions.

Pavlov and his school (cf. Pavlov, 1941), and Watson (1924) with the behaviourists, began in their particular way not only to influence methods of study, but also to be influential in producing a more objective attitude in the study of behaviour, particularly in the earliest years of life. With the minimum of philosophical interpretation it was possible to observe the growing capacities of a child viewed entirely as a creature reacting to stimuli and yet reaching out to higher capacities under the influence of its maturing nervous system. By the observation of large numbers, behaviour charts for each year could be constructed, allowing for early diagnosis of defectiveness or, at least, of retardation.

But by these means alone the dynamics of child life could not be fully understood. The work of Bridges (1925) and others did indeed show that the child's emotions undergo modification and reorganization, but the inner teleology was not comprehended until psychopathology, in the hands of Freud and the derivative schools, added yet another dimension for the study of child life and mind.

Yet a third co-ordinate on which the life of the child depends is the social nexus. Since the time of Herbert Spencer it has been increasingly realized that the human subject derives his essential qualities not solely from the natural environment, but from the environment made up of other persons enjoying the same cultural and economic opportunities, and suffering the same restraints and frustrations that a relatively fixed social and economic structure imposes. The impact of cultural and economic forces has very special effects on the child. The parents are the transmitters of a social inheritance based on ideals of conduct and a tangle of prejudices. The socio-economic status of the parents in a class-stratified society imposes on the child advantages here and disadvantages there, varying opportunities of education, differences of space for living, sleeping and play, different degrees of nutrition. The characteristics, both mental and physical, of the environment affect the growing child in different measure,

from infancy to his entry as an adolescent into the open community life outside the family. These considerations are, of course, as important in adult life as in childhood, but the forces in the family as the first field structure, and in society as the extended field structure, in which the child behaves, exert special force because of the child's plasticity and dependence.

## 2. Etiological Roots

Reviewing these dimensional aspects of modern psychiatry, we can say that a full study of the child and its disorders can be arrived at only by a close inspection of four essential etiological roots: (i) the organic-biological, expressed in genetic endowments or defects, and the assaults upon this by disease or injury in early childhood; (ii) the psycho-biological, expressed in the unfolding, maturation, and inhibitory forces of the child body-mind displayed when we study the endowments of the child; (iii) the family influences which restrict the child's instinctual development; (iv) the social forces which the parents exert as cultural carriers, and which later appear in the social world of the community expressed through the school, the neighbourhood, and, later, in the still wider spheres of influence of society in general.

Recognition of these dimensions has been the basis of the team studies which make prognosis, diagnosis and treatment possible. There can be no one person who can carry the weight of, let alone manipulate, all the diagnostic instruments which this multiple approach implies. In any case, we need the initial skills of the paediatrician and neurologist to eliminate those systematic and metabolic disorders which have emotional and behaviour sequelae. For example, coeliac disease, with its debilitating and stunting effects, has frequent behaviour repercussions; epilepsy tapers off from major attacks to petit mal and episodic storms of temper and stuporose attacks. The electroencephalogram will doubtless, after further statistical studies, show us what types of dysrhythmia can be regarded as correlates of neural and mental symptoms. Encephalitis lethargica has a variety of mental sequelae, from minor changes of character to the grossest disorders of behaviour of an asocial and antisocial type. Disorders of the corpus striatus and thalamus, in which the presenting symptoms are not unlike hysteria, are known to present diagnostic difficulties, and temporo-parietal disorders have occasionally been the basis of obsessional-compulsive behaviour.

When we turn to the field of intelligent behaviour, we may, at one end, be confronted with organic brain states such as agenesis of the cortex or nodular sclerosis (deduced clinically or confirmed post mortem), from which, by the use of mental tests, we pass successively through manifestations of impoverished intelligence and average endowment to near genius at the other end. Special disabilities, such as agnosia or apraxia—of the nature of congenital imperceptions and of lack of capacity for symbolic thinking—make their appearance in delayed speech in early childhood or as scholastic handicaps in the schoolroom. This field is the proper study of the educational psychologist, skilled in the administering and interpretation of standard verbal and performance tests.

These two dimensions, neuropsychiatry and psychology, and their specialist team workers belong, as it thus appears, to the basal psychophysics of the affected child.

## 3. Psychological and Social Problems

The psychiatrist proper would appear to concern himself firstly with the broad study of behaviour and character in their devolutionary aspects. This is in the nature of an iconography of diseases or reaction types derived from the study of adult psychiatry. Nevertheless, although the young child, and certainly the adolescent, can suffer from disorders of conduct and thought analogous to the disorders of adult life, the child, in virtue of his immaturity and subjection to adult control, presents certain peculiarities which do not fall within categories of adult psychiatry; in fact, the latter may prove to be derivatives of the life and vicissitudes of childhood. Apart from the organic substrate, and assaults on the nervous system which, even in childhood, occasion dementia, obsession and early schizophrenia (dementia praecocissima), the early struggles of the child in its efforts to master instinctual discharges have shown us that an essential dimension for understanding emotional development and its aberrations can come only from the construction of a psychopathology which explains the moulding of the early years and the subsequent shaping of character and its deviations.

The main concern of the child psychiatrist today is to obtain such a careful case history as will give a general line of the development of the child in each instance. In the vast number of cases, such history-taking eliminates in the first place those organic diseases and disorders of nutrition which cause or aggravate behaviour disorders. This leaves a majority of children whose troubles are occasioned by gross mismanagement at the critical periods of life and/or are due to causes closely concerned in the intimate psychological unfolding of the child's instinctual life. This instinctual life—the satisfaction of fundamental interests—is woven into the child's relations with parents, brothers and sisters. Indeed, the child, at first one with its mother, gradually forms its own life of reaction under maternal tutelage. The early nutritional and excretional activities, and the controls exerted by nurture over these activities, subject the child to a variety of stresses and frustrations which lay down the first dynamic structures of character, or produce the first neurotic, and even psychotic, reactions. This constitutes the first layer of human psychopathology, and in it is woven the first evaluations of experience, good and bad, which form the moral and social nature of the child. Child psychopathology was at first derived from adult psychoanalysis; but inasmuch as these therapeutically designed studies revealed the childhood reactions of each patient, a child psychopathology was born which obviously called for checks, in the form of direct study of the disordered child. It is clear that adult analysis cannot be carried out on the problem child, and the very young child is hardly linguistically endowed to articulate its stream of memories and feelings. In the hands of Hug Hellmuth, Anna Freud and Melanie Klein a technique was evolved which used the language of the child, namely play; the aspirations, resentments, loves and hates are expressed in the fantasy revealed in play. It is claimed that this technique has confirmed much that has been learnt from the analysis of adults and has added new data, new emotional relations nearer the child's raw experiences before adult social reactions and obligations born of maturity or quasi-maturity have disguised and complicated simple patterns.

Although this play-technique is the radical instrument in the hands of child psychiatrists, it cannot be universally applied to the many that need it, because of the length of time required and the small number of skilled physicians available. Nevertheless, the discoveries made through its application to the few have given us clues for elucidating the problems of the many. The study of the life-story and presenting symptoms of the child treated by play analysis gives us indications of the mechanisms of other children not so analyzed. Psychopathology and social studies, linked together, give us a useful twofold instrument for the examination of problem children and problem families. That is to say, by social studies of family relations viewed broadly, and by inferences from psychopathology as to the difficulties of the individual child, we can act in an advisory capacity to parents by suggesting changes in parental technique; this means largely changes in parental attitude. It is said that the problem parent produces the difficult child. This partial truth may lead the psychiatrist from time to time to recommend psychological treatment of the parent rather than of the child. It is only a partial truth because parents may, within normal limits, have done well by their children, but in the early years of life it may well have been that the child, unable to tolerate frustrations imposed quite light-handedly, has constructed in fantasy a picture of his parents which cannot be easily accepted because of its mixture of good and bad elements.

#### 4. Problems of Child Guidance

This method of handling difficult children (and sometimes problem parents) has been designated Child Guidance, and is a technique which calls for a team effort of psychiatrist, psychologist and social worker. Largely advisory in aim, this technique is analytic and synthetic in method or means. It has a variety of problems to handle, and these can be roughly divided as follows:

##### A. Psychiatric and Educational

1. Problems of intelligence and education. Testing for special abilities, and for disabilities which cause educational difficulties and their behaviour repercussions.

##### REFERENCES

- Binet, A. & Simon, T. (1911) *La mesure du développement de l'intelligence chez les jeunes enfants*, Paris  
 Bridges, J. W. (1925) *An outline of abnormal psychology*, Columbus, Ohio

2. Problems of character and neurosis; these may have few family causes in the gross sense. The major problems are found to be:

(a) Disorders of functions of the body, which are expressions of emotional causes.

(b) Disorders of mental process—producing depressions, phobias, compulsions, separation anxieties, timidity and lack of capacity for co-operation.

(c) Disorders of behaviour, such as resentments, hostilities, temper tantrums, episodic flights from school and home.

(d) Disorders of a social nature, expressed in a variety of delinquent acts: pilfering, breaking in, damaging property; sexual abnormalities involving other persons.

##### B. Social

1. Problems arising from unhealthy milieu or economic distress.

2. Problems arising from gross breach of the family structure, i.e. loss of one or other parent by separation, divorce or death. To this must be added the psychological results of the stepmother or stepfather problem, and the dilemma of the adoptive mother. (The war has presented additional problems resulting from: evacuation, the new work and obligations thrust on mothers, the discontent and disillusionment of the father returned from war service.)

It will be obvious that all these situations are at one and the same time problems of the individual and of the primary family group, as well as problems of the family as a field of tension subject to the social tensions of the locality and the community.

In the technique of child guidance we are confronted by both these serious and interlocking problems, and also by great opportunities for clarifying those socio-psychological problems which, when solved, or at least scientifically tackled, will open new avenues for the study and advancement of human welfare.

The Children and Young Persons Act, 1933, states: "No child under the age of eight can be guilty of any offence." It defines a "child" as a person who in the opinion of the court before whom he is brought is under the age of fourteen, and a "young person" as one aged fourteen and under the age seventeen. In criminal statistics both these groups are considered under the term "juvenile offenders".

## 1. Statistical Data

During the year 1945, the last for which figures are available at the time of writing, the incidence of crime in England and Wales in the age-group eight and under fourteen years was 22,922 males and 1,500 females. In the age-group fourteen and under seventeen the figures were 17,349 males and 1,732 females. The number of delinquents and criminals per 100,000 of the population at different ages or age-groups in both sexes was highest at the age of sixteen years. Thereafter the figures show a progressive decline. Although the juvenile delinquent is usually no more than a socially immature nuisance he may become a persistent offender and a menace to society unless his social, physical, mental and moral development is directed towards social usefulness. The methods adopted by Magistrates' Courts when dealing with juvenile offenders guilty of indictable offences have therefore special significance. In round numbers, the figures of disposal were as follows:

*Under the age of fourteen*, 41 per cent were placed under the supervision of a probation officer, 38 per cent were dismissed or bound over without supervision, 8 per cent were sent to Approved Schools,<sup>1</sup> and 11 per cent were fined. *Between the ages fourteen and seventeen*, 41 per cent were placed under the supervision of a probation officer, 26 per cent were dismissed or bound over without supervision, 11 per cent were sent to Approved Schools, and 19 per cent were fined.

<sup>1</sup> [Schools approved by the Secretary of State under Section 79, Children and Young Persons Act, 1933.—Ed.]

## 2. Causal Factors in Delinquency

The nature of juvenile delinquency is complex and may be the result of a combination of innate, social, physical, mental and moral variables.

### a. Innate Factors

There is general agreement with Burt's early statement (1925) that a criminal disposition is not directly inherited. Indirectly, the interaction between heredity and environment may establish a "crimogenic" disability manifesting itself through mental disease, mental defect or neuropathic tendency, or by character anomalies which adversely affect social life. Parental alcoholism, for example, as suggested by Young (1938) and others, is probably more often one of several alternate agencies having an adverse influence on conduct, rather than the specific cause of crime in the offspring, though some cases may be properly attributed to its exclusive influence.

### b. Social Factors

There may be little difference between the misconduct of a public school<sup>2</sup> boy and that of a boy from an elementary school. The former may be disobedient and the latter delinquent according to the correctional measures adopted, educational or magisterial.

Modern research has not materially altered the view that overcrowding, poverty and family strife may be causal factors among juvenile offenders. Bagot (1941) considered overcrowding was strongly associated with delinquency in Liverpool, and that it probably operated by driving large numbers of children into the streets when they should have been in bed. East, Stocks & Young (1942) found that of 4,000 male delinquents between the ages of 16 and 20, from the London and adjacent areas, 496 were 16 years of age, and that the person density per room of the habitation at this age was mostly below 2 persons per room. The density per room at 16 was significantly greater than at later ages, and it seems probable that the density below this age would be still greater.

Burt (1925) found 16 per cent of delinquent children from the London area belonged to families who were definitely on the poverty line. Bagot (1941) concluded that poverty was a vital factor among the causes of delinquency in Liverpool. East *et al.* (1942) found that, of the above-mentioned 496 delinquents aged 16, no less than 142 came from a poor-class district, 26 from a poor and better, 313 from an artisan and only 15 from a superior district. It was found that among delinquents aged 16, the convictions per head increased step by step as the maximum wage increased. It may be noted that the satisfaction or dissatisfaction of a boy with his surroundings depends to some extent upon the standard he expects, and that the same environment may be congenial to some boys and unsatisfactory to others. Individual adaptability as well as habituation may modify dissatisfaction and make an environment acceptable. Miller (1944) states that some of the most startling cases of juvenile delinquency that he has investigated amongst the moderately poor have sprung from satisfactory homes, that

<sup>2</sup> ["In England . . . In modern use . . . large boarding-schools, drawing from the well-to-do classes, pupils who are prepared mainly for the ancient universities or for the public services, and also . . . some large modern schools with similar aims." *The shorter Oxford English dictionary*. Oxford, 2nd ed., 1936.—Ed.]

is to say homes in which there has been no overt disorder or disruption.

Apart from the effect of so-called broken homes, mention may be made of unemployment, failure to join a boys' club, and the influence of associates. It is generally agreed that juvenile delinquency is to some extent an expression of indiscipline, and it is important to consider the quality of the control to which the delinquent has been subjected, as well as his subsequent reaction. East *et al.* (1942) found that of 3,987 offenders aged 16 to 20 in whom a record of control was available there was in each age-group—except for a small number under strict and repressive control—a diminishing amount of resistive action as age advanced.

#### c. Physical Factors

Apart from encephalitis lethargica and certain other diseases, various estimates are given concerning the relation of physical health and juvenile delinquency. Burt (1925) found that defective physical conditions were, roughly speaking, one and a quarter times as frequent among delinquent children as they were among non-delinquent children from the same schools and streets. And he states that regular medical inspection and treatment of all school children, as a matter of routine, has done much to forestall crime and misconduct during later life. Bagot (1941) concluded that his survey did not show inferior health as an important factor in causing delinquency. Pearce (1944) believes that juvenile delinquents lack vigour and robustness. He observes, however, that in many delinquent children the reverse is true and the very quality of their exploits indicates dynamism. The London data of East *et al.* (1942) showed no tendency for the lads to differ in stature from the general population of town dwellers of the same ages. The mean weight of the London delinquents was well below that of London-employed males of similar ages, but was consistently above the general urban industrial average. There was no certain evidence of any association of criminal tendencies and underweight. At age 16, lads with three or more previous convictions registered a statistically significant excess in the mean chest measurement over lads with fewer convictions. The fact that physical inferiority is sometimes related to marked social achievement is generally recognized. There is often, of course, no association between the physical disease of an offender and his offence.

#### d. Mental and Moral Factors

The causal relation of mental defect and juvenile delinquency has been variously estimated. In his early researches Burt found 8 per cent of his delinquent children were definitely

defective. Lewis (1944) emphasizes the fact that it is impossible to estimate even approximately the number of mentally defective persons in the certified institutions in Great Britain who were potential criminals and who would, sooner or later, have appeared in the courts had they remained in the general community. Bagot (1941) concluded that backwardness is strongly associated with delinquency. East *et al.* (1942) found that among the London delinquents the proportion who were mentally defective (5 per cent) was very much higher than would be expected in a random sample of the general population. Miller (1944) states that most observers agree that intelligence-level is a factor in the retention of normal standards of social behaviour but does not alone occasion delinquency. Of the 496 London delinquents aged 16, only 4 were found to be suffering from insanity, 3 from epilepsy and 2 from psychoneurotic disorder. Emotional and temperamental disabilities, however, are frequently associated with juvenile delinquency.

Except for a few cases of moral defectiveness (i.e., ethically aberrant psychopathic personalities) many of the so-called moral deviations of behaviour associated with delinquency can be only loosely defined. Excluding examples of psychopathology, some are attributable to parental carelessness, and may be the result of parental disregard for the rights of others, or of a more expressed determination to leave correction to the teacher when the child goes to school. Any discussion on the increase in juvenile delinquency today must differentiate between naughtiness and the more serious forms of delinquency. The latter can hardly be avoided if the delinquent's associates approve of his misbehaviour, and if the general moral standards of modern adults remain at their present low level. However this may be, as with the body so with the mind: scarlet fever may select only one member of the family, and delinquency may be due to causes which leave others in the family unscathed. The many contradictory conclusions of experienced observers leave one in no doubt that every juvenile delinquent presents a special diagnostic, prognostic and therapeutic problem, and that causal factors may reinforce or cancel out each other.

### 3. Treatment

Reference has been made to the broad methods adopted by juvenile courts when dealing with delinquency. Medical psychologists aided by trained social workers have a contribution to make in a proportion of exceptional cases. An immediate requirement seems to lie in greater preventive efforts. This may follow if the world's present moral apathy is superseded and genuine citizenship becomes an important educational study.

## 1. The General Problem

According to the estimate of the Registrar-General, persons over the age of 65 will in 1951 form 11·6 per cent, and by 1971, 17 per cent of the population of England and Wales, unless there is a change in the present trends of birth and mortality rates. It is therefore not surprising to find that in recent years increasing attention has been paid to the social and medical care of the aged, and an extensive study was undertaken for the Nuffield Foundation by a Survey Committee on the Problems of Ageing and the Care of Old People under the chairmanship of Mr. B. Seebohm Rowntree. The report of this Rowntree Committee was published under the title *Old people* (Rowntree, 1947), and the social and medical issues raised have stimulated considerable public interest.

Further to this study, Sheldon (1948) carried out a medical survey in Wolverhampton, an English Midland town with a population of about 150,000, on one of the random samples of men over 65 and women over 60 which had been investigated from a social angle by the Rowntree Committee. Information was collected from 477 people during personal visits, and supplemented in many cases by the opinions of friends and medical attendants. The wealth of data obtained was analyzed under the three headings of "Physical state," "Mental state," and "Domestic structure," but the interdependence of all findings in determining the status of health of the individual emerged clearly. To give only one instance: deafness and vertigo due to degenerative disorder of the internal ear were frequently found to produce disorientation in the dark, sometimes precipitating nocturnal confusional episodes.

Turning to the mental state of old people living at home, the picture is, on the whole, a cheering one for the reader accustomed to dealing with patients suffering from senile deterioration in mental observation wards and hospitals. Only 3·8 per cent of the persons visited presented evidence of mental breakdown; 11·2 per cent showed slight impairment of their mental faculties; 3·2 per cent were eccentric in their habits, without suffering from intellectual deterioration; the remaining 81·8 per cent were classed as fully normal mentally. Moreover, a fair proportion of these old

folk left a distinct impression on the investigator's mind of unusually fine and vigorous characters. It is reassuring to have confirmation, scientifically obtained, of the impression gained in everyday contact with old people, that the overwhelming majority retain their mental faculties to the full.

On the other hand, Aubrey Lewis (1946) pointed out that the statistics of the Board of Control (England and Wales) showed that the annual number of 'first attack admissions' of patients over the age of 65 in the years 1907 and 1937 increased from 821 to 1,187 for males, and from 897 to 1,522 for females. An analysis of the incidence rates per 100,000 of the population over 65 gave anomalously low values, especially when compared with figures in the USA, which show steep increases of 'first admission rates' with rising age. Lewis presented convincing evidence to show that the comparatively low incidence rates of first admissions of patients over 65 in this country were due to the retention in public assistance institutions of many patients who should have been admitted to a mental hospital. Moreover, in the area of the London County Council (1947) accommodation has been provided for cases of senile dementia at the Tooting Bec Hospital. To this institution, with nearly 2,500 beds, elderly patients with mental disorders have been admitted either under a section of the Lunacy Act of 1890 which deals with the detention of harmless persons of unsound mind in workhouses, or, if they are over 70 years of age and with no record of previous certification, without formalities under the Lunacy Acts.

A more limited study was undertaken in Scotland by the present writer (Post, 1944), who analyzed the admission figures of the Royal Edinburgh Hospital for Mental and Nervous Disorders and found that the proportion of patients admitted over the age of 60 had steadily risen from 14·35 per cent (14·3 % males, 14·4 % females) in 1903 to 30·9 per cent (27·9 % males, 33·0 % females) in 1942. When these trends are viewed in conjunction with the estimated future increase in the number of old people, we are forced to agree with the conclusion that "We must regard the mental disorders of the elderly as likely to be responsible within the next thirty years for the bulk of the patients admitted to mental hospitals." (Lewis, 1946)

## 2. Senile Deterioration

There are few psychiatric disorders which may not occur, either as a recurrence or for the first time, during senescence. Especially, first attacks of a manic-depressive psychosis in an episodic or chronic form are not at all uncommon, and convulsive therapy has been employed to an increasing extent in aged patients (Mayer-Gross, 1945). The so-called presenile dementias, though by definition beginning before the onset of senescence, frequently manifest themselves after the age of 60. Contributions to the symptomatology of these disorders (Stengel, 1943) and their relationship to senile dementia (Newton, 1948) have recently been made in Great Britain. In the present survey, we shall concern ourselves only with the much more common mental disorders due to senile and arteriosclerotic brain changes. Moreover, it is not possible to give a full account of all the aspects of deterioration from normal senescence; it is merely intended to give some information on the trend of work done recently in Britain.

### 3. Survey of Psychological Work

Psychological studies of ageing and senility were reviewed and critically examined by Margaret Davies Eysenck (1946), who concluded that the studies undertaken so far have been largely exploratory, and pointed out the fallacy of drawing conclusions on the mechanism of the psychology of ageing from the comparison of groups of young people with groups of old people; she advocated "large-scale longitudinal follow-up studies" designed to reveal the intellectual, emotional, temperamental and attitudinal changes occurring during an individual's life.

Her own contribution (Eysenck, 1945) has been an exploratory study of mental organization in senility, in which she applied factorial analysis to the results of 20 psychological tests given to 84 co-operative patients with senile dementia. Re-test reliabilities were established for the tests used, and three group factors concerned with speed, memory, and physical strength, respectively, as well as a general factor, emerged. This general factor presented a picture of mental organization which differed greatly from that found in normal adults and was thought to be due to the differential deterioration in senile patients of what Cattell called "fluid" and "crystallized" abilities. This point was illustrated particularly clearly by the finding that whereas seniles scored considerably above the 14-year-old level on the Mill Hill Vocabulary Test (a test representative for "crystallized" ability), only the 8-year-old level was reached on Raven's Progressive Matrices Test, which is a highly representative test for "fluid" abilities.

These two tests were used by Foulds & Raven (1948) in an attempt to draw inferences concerning normal changes in mental ability for ages up to 60. Broadly speaking their results were "... in agreement with the generally accepted view that from about the age of 30 onwards a person's ability to understand new methods of thinking, adopt new methods of working, and even to adjust to new situations, steadily decreases, whereas he is normally able to recall acquired information long after his capacity to adapt to new situations has begun to decline." The authors stress the need of information concerning the normal changes after the age of 60.

### 4. Symptomatology of Deterioration

Mildly deteriorated senile patients are more often encountered by the general practitioner than by the psychiatrist. Sheldon (1948) examined the symptomatology of men and women with a mild impairment of mental faculties who made up 11.2 per cent of his random sample of old people living at home. He summarized his observations in giving as early signs of senile mental failure: "Some restriction of activity, with a tendency to apathy; a mild disturbance of appetite; a definite liability to change of mood, especially apt to express itself by depression of spirits; a slight failure of memory; a tendency to aberration of talk—either in the direction of loquacity and rambling speech or in a slowness of speech; a tendency to morbid anxiety, and a diminished desire for occupation and capacity for self-care."

It is at this stage of mild senile deterioration that asocial behaviour disorders may emerge for the first time in a person's life. Though Norwood East (1944) draws attention

to "... the well-known fact that the incidence of crime per 100,000 of the population of the age or age groups consistently decreases after thirteen as age advances", he quotes Goring's (1919) analysis of the age incidence of 682 first offenders convicted of serious offences as demonstrating that between the ages of 60 and 65 there is a transient period of exacerbation in an otherwise rapidly diminishing tendency towards crime. Certain types of offence such as homosexual acts with boys and attempts at suicide were relatively more frequent in persons over 60 than in younger age-groups, and East (1944) states that "... clinical experience suggests that in many cases as one gets older personality seems to be a more important crimino-genic factor than environment. In young and middle-aged persons a first offence is only occasionally an early indication of mental abnormality; in elderly persons it should at once arouse doubts as to whether it is the result of senile degeneration." The difficulties which are encountered in medico-legal practice in determining criminal responsibility of aged offenders are discussed fully, and East expresses the opinion that a knowledge of the mental background of such a person may suggest the most suitable way of dealing with him, and of protecting society from his misconduct<sup>1</sup>.

In Sheldon's (1948) sample of old people living in their own homes 3.8 per cent suffered from severe mental deterioration, and several of the subjects in this group had to be admitted to mental hospital in the course of the investigation. Post (1944) found that by far the commonest immediate cause for hospital admission was a confusional state, apparently acute in onset; in addition, deterioration of personal habits made transfer to a mental hospital necessary much more frequently than did paranoid, aggressive, or suicidal tendencies. Using Rothschild's (1941) criteria for the clinical differentiation of senile and arteriosclerotic psychoses, it was possible to show how much more favourable was the immediate prognosis—in terms of discharge from hospital—in arteriosclerotic as compared with senile cases. Review of the histories and clinical states suggested that patients broadly fell into two groups: in one, a simple dementia, either on a senile or an arteriosclerotic basis, developed in an inconspicuous fashion, whereas in the other group florid psychotic symptoms, often bizarrely paranoid or depressive in type, dominated the picture until a more profound stage of dementia supervened.

### 5. Etiological Considerations

In agreement with earlier work, it has been found that a large proportion of people developing senile or arteriosclerotic deterioration had been ill adjusted psychologically all their life. Lewis & Goldschmidt (1943) discovered well-marked personality difficulties in 67 per cent of their Tooting Bec cases, while Post (1944) gives a figure of 62 per cent; the latter was also able to confirm that patients who exhibited positive psychotic symptoms as well as dementia had, on the whole, been far more seriously maladjusted throughout life than those suffering from a simple dementia only. The importance of the constitutional factor is further supported by evidence of the familial incidence of the disorders under discussion. Confirming the findings of Meggendorfer

<sup>1</sup> [The care of the mentally defective criminal is discussed by Sir Norwood East in this number of *British Medical Bulletin* (BMB 1304).—Ed.]

(1926) and Weinberger (1926), 25 of Post's 78 cases (32.1 per cent) of senile or arteriosclerotic mental disease had a positive psychiatric family history; in 15.4 per cent this was one of senile or arteriosclerotic deterioration, and if relatives who had suffered from strokes, allegedly without psychiatric complications, were included, the figure for positive family history rose to 24.4 per cent (Post, 1944).

The main practical question which the study of the mental aspects of senescence throws up is, whether there is anything we can do to prevent or retard the onset of senility. Recognition of the importance of constitutional factors such as heredity and personality-structure may help to indicate the type of person on the danger list for mental deterioration; but if these considerations are allowed to influence our therapeutic attitude unduly, they may be as harmful as is preoccupation with brain damage to the exclusion of the dynamic aspects of personality. Leaving aside as self-evident the importance of maintaining general health and of attending to special physical defects, etiological factors operating from the environment would appear to be the only ones which can be removed or modified.

Sheldon (1948) was able to compare the social circumstances of normal aged persons with those of people showing slight mental impairment (11 per cent of his sample). The members of this group, demonstrating as it were senility *in statu nascendi*, were relatively more afflicted with the burdens of the widowed state, loneliness and domestic anxiety than normal old folk. A feeling of loneliness, in particular, was definitely associated with a mild degree of mental impairment and in a large majority of cases was due to recent loss of the marital partner. On the other hand, a considerable proportion of the subjects who felt lonely were not in fact living alone, and Sheldon considered the question as to how far anxiety and a sense of loneliness were symptoms, rather than causes, of mental impairment. He came to the tentative conclusion, however, that some individuals are so constituted in their personality as to be more prone to feelings of loneliness and anxiety than others, and that they will react more deeply to an unfavourable social environment; the resulting upset of emotional balance might then initiate a train of deterioration of personality and intellect. In the senile dementia patients studied, after their admission to hospital, by Lewis & Goldschmidt (1943), failure to retain a place in the community, to remain a member of a family, or to have an appreciated share in the life of some household or working group, was a common finding. This defect of social integration was looked upon as powerfully adverse to mental health; although in some of the cases it had been the outcome of a wayward and difficult personality, the authors thought that in many, the breaking down of social integration had been the unavoidable consequence of the narrowed circle, bereavements, and an incapacity for forming new habits and associations.

## 6. Therapeutic Considerations

All branches of medicine must make their contribution towards the maintenance of health during old age. The psychiatric approach is determined by an endeavour to postpone or mitigate the effects of brain changes on personality functions or, in other words, to influence the rate and extent to which senescence changes into senility. In

the psychiatric care of the ageing patient attention is paid to the emotional state, and attempts may be made to modify attitudes and neurotic tendencies which may have existed for many years but whose exacerbation is frequently a danger-signal of impending senile deterioration. Though in selected cases this approach may be very helpful, an attempt to influence etiological factors in the environment of the ageing person is usually more feasible. The feeling of loneliness can often be combated by interpreting the patient's behaviour to his friends and by encouraging them to allow him or her to take a more active part in the family circle. The psychiatric social worker will, in addition to her work with the patient's family, help him towards the cultivation of hobbies and put him in touch with one of the increasing number of clubs for old people. Beyond outlining these general principles, no further elaboration of the practical approach will be attempted, because basically the problem is too large to be solved in terms of treatment of the individual patient. In the discussion, at the 1948 Annual Conference of the British Medical Association, on the early recognition and treatment of senile deterioration, all the speakers stressed the paramount need for re-orientation of our social attitude towards the aged; instead of being obliged to retire at a fixed age, old people should be retained as long as possible in carefully selected and reasonably gainful employment. Earlier Mackintosh (1947) had even gone so far as to suggest the introduction of selection boards and the application of the methods of child guidance in old age.

## 7. Present Trends of Research

A serious decline in the standard of living in Great Britain would, in fact, inevitably result from the increase in the number of old age pensioners and the simultaneous decrease in the size of the working population, which have been predicted by the vital statisticians. One way of keeping national production and income at the present level might be by raising the retiring age and thus retaining elderly people in productive employment.

At the Nuffield Research Unit into the Problems of Ageing, which is under the direction of Sir Frederic Bartlett at Cambridge, investigations are in progress on the issues involved in maintaining the efficiency of men in later middle age employed in industry, and the work of the Unit has been concerned mainly with the timing and detailed analysis of some skilled operations, both motor and mental; special attention is being paid to the investigation of problems of re-training. At the Department of Psychological Research of the Crichton Royal, the mental hospital at Dumfries, J. C. Raven has been able to standardize the Progressive Matrices and Mill Hill Vocabulary Tests for British people of all ages up to 65, and enquiries are in hand concerning normal and abnormal changes after that age.<sup>2</sup> On the clinical side it is hoped to establish a geriatric unit at the Bethlem Royal Hospital, Beckenham, and the Maudsley Hospital, London, where problems of early deterioration will be studied from psychiatric, psychological, and social angles. Thus work is proceeding along fresh lines of approach which in time should lead to an increasing understanding of the mental aspects of senescence.

### A. PROVISIONS FOR THE STUDY AND TREATMENT OF THE CRIMINAL

Since the beginning of the present century psychological and psychiatric studies in Great Britain have added valuable information towards a better understanding of the criminal, and of the many problems involved in the prevention and treatment of crime. Modern sociological and penological investigations also have advanced our knowledge. But no single line of approach can do more than provide the investigator with some of the clues necessary for an understanding of the subject.

Studies have been carried out by, or with the consent of, Government departments, civil and military; by societies and other bodies; and by individuals. Sometimes investigations inaugurated for another purpose throw light upon

the causation and prevention of criminal behaviour. Finally, the Executive Authority is constantly assessing the value of new proposals and ideas with a view to incorporating into the administrative machine such as may prove practical and progressive.

#### 1. Official Studies

The Prison Commissioners frequently explore new methods in the training, education, rehabilitation and after-care of prisoners. A detailed account of the progress made is published yearly by His Majesty's Stationery Office (His Majesty's Prison Commissioners Annual Reports). Other studies have been carried out by teams and individuals. For example, in 1933 the Home Office, with the co-operation of fifteen Magistrates' Courts, began an enquiry with the object of ascertaining how many offenders placed on probation commit further indictable offences during a period of three years after the probation is ended. In the same year another investigation examined the files in the Criminal Record Office of 20,667 persons over the age of sixteen found guilty of offences sufficiently serious to warrant the taking of finger prints, and who had no previous offences recorded against them, in order to estimate the proportion who were free from further charges during the subsequent five years. The work has been continued and the latest published results refer to 139,862 offenders (Report of the Commissioners of Prisons, 1947).

Before 1933 a medical psychologist (Pailthorpe, 1932) issued a report on studies in the psychology of delinquency. The work was carried out under the auspices of the Medical Research Council with the co-operation of the Home Office.

Team work by Prison Medical Officers, lasting in some cases for several years, enabled an anthropological survey of the English convict to be published (Goring, 1913). A report on the psychological treatment of crime appeared in 1939 (East & Hubert, 1939), and a statistical study of 4,000 adolescent criminals in 1943 (East, Stocks & Young, 1943). Individual medical officers have published books on the subject of crime and criminals, and have written numerous papers for the scientific journals.

The Second World War enabled psychiatrists attached to the fighting Services to study large groups of men who became mentally disturbed by employment as combatants. Many of the disturbances presented themselves as problems in delinquency. Early in 1942 the Navy opened Kielder Camp as an observation and treatment centre for mentally abnormal ratings, some of whom were delinquents. Many interesting papers by Service psychiatrists on different aspects of the association between combatant service and

criminal behaviour have appeared in the medical journals. Negative studies also have been significant. For example, the medical officers of a submarine flotilla collected material which tended to show that the submarine service attracted a stable type of man who maintained a high state of morale and that psychiatric illness in its personnel was very small.

## 2. Studies by Societies

The Medico-Legal Society frequently, and other societies occasionally, discuss at their regular meetings problems concerning criminals and the prevention and treatment of crime. Lectures on forensic psychiatry have been given for many years at the Maudsley Hospital Medical School (now the Institute of Psychiatry, University of London) in connexion with the postgraduate course for the Diploma in Psychological Medicine (D.P.M.). Lectures on criminology are also now given in the Institute of Psychiatry at the Maudsley Hospital, and postgraduate students on the clinical staff of the hospital receive as part of their normal training opportunities of studying the forensic aspect of psychiatry at certain London prisons.

The Howard League for Penal Reform has long studied criminals and their treatment, and in its journal reviews modern methods for the prevention of crime and delinquency. Recently an International Committee of the Howard League for Penal Reform (1947) published in book form a policy which it is suggested should be applied to the Juvenile Courts. The Tavistock Clinic and the Institute for the Scientific Treatment of Delinquency, as well as other psychiatric clinics, have developed researches which include the diagnostic and therapeutic approaches to delinquency.

## 3. Studies by Individuals

Psychiatrists attached to mental hospitals, having special opportunities for study, contribute to the scientific journals papers which discuss certain aspects of the problem of the association of mental disease or defect and criminal behaviour. In recent years magistrates and others, sometimes aided by the generosity of the trustees of endowed funds, have published the results of individual research. And although some of the writings fail to avoid a biased presentation, many provide a stimulus to those whose minds are progressive and imbued with the importance of crime as a social problem.

## 4. Extraneous Studies

In 1934 the Carnegie United Kingdom Trustees published a report (Bell, 1934) on the Junior Instruction Centres which were established to prevent deterioration or demoralization likely to arise from unemployment. Amongst other matters the investigation considered whether the Centres had helped to counteract the increasing amount of juvenile crime. In 1943 the Hygienic Committee of the Women's Group in Public Welfare issued a report dealing with an investigation into the domestic habits and customs of certain town dwellers evacuated during the war. The report showed a broad, humane and factual approach to many matters; from it emerged further reason to believe that juvenile delinquency appeared to be, at least in part, another of the problems due to parental failure. A report (Stephens,

1945) issued by the Pacifist Service Units on an experiment in the social rehabilitation of problem families stated that, in a certain group of cases investigated, mental and psychological difficulties were invariably found, and that psychiatric treatment proved ineffective mainly because of the absence of a satisfactory home background. It was also found that the instability of many patients rendered continuous treatment impossible.

The Burden Neurological Institute, in association with the Society for the Study of Addiction (to Alcohol and Drugs), and aided by a grant from a body of interested persons, is conducting research into the nature and causation of alcohol addiction; the findings may influence the treatment of the alcoholic offender.

The catholicity of the studies in progress is made apparent by the fact that eugenic research and the experience of Marriage Guidance Councils provide relevant information. The Civil Courts add their quota. A distinguished County Court Judge has recently stated (Earengy, 1948) that in tenement dwelling-houses parental influence decreases to the vanishing-point, and that he is convinced that much of the looseness of behaviour tending to immorality and crime in (but by no means confined to) the classes brought up in tenements is substantially due to bad housing conditions.

## 5. Studies by the Executive Authority

These are concerned with the trend of modern thought in the prevention of crime and the treatment of the criminal, and relevant matters are periodically reviewed by the Home Office Advisory Council on the Treatment of Offenders.

## B. PROVISIONS FOR THE CARE AND TREATMENT OF MENTALLY DEFECTIVE AND MENTALLY ABNORMAL CRIMINALS

### 6. Mentally Defective Persons

The Mental Deficiency Act, 1913 gave Criminal Courts power to take steps to place a mentally defective offender under guardianship, or cause him to be detained in an institution for defectives. It also authorized the Home Secretary to transfer to an institution for mentally defective persons a prisoner undergoing a prison sentence if he is satisfied, on the certificate of two medical men, that the prisoner is mentally defective.

Institutions for mentally defective persons are of two kinds: *State institutions* are established and maintained by the Board of Control<sup>1</sup> for defectives of dangerous or violent propensities; *Certified institutions* are institutions in respect of which a certificate has been granted under the Act to their managers to receive defectives.

### 7. Insane Persons

If they are so insane as to be unfit to plead, insane offenders are detained in a mental hospital. An offender who is found to be guilty but insane is also similarly detained. A prisoner who is found to be insane during a prison sentence is certified as such by two doctors and two visiting Justices,

<sup>1</sup> [The Board of Control was created by the Mental Deficiency Act of 1913. As from July 1947, the administrative functions of the Board of Control were transferred to the Minister of Health, the Mental Health Service thus being integrated with the National Health Service.]

An article on mental health and the National Health Service is to appear in the next number of the Bulletin.—Ed.]

## THE LAW RELATING TO TEMPORARY TREATMENT IN MENTAL HOSPITALS

CYRIL F. PENTON M.A.

*Legal Senior Commissioner  
Board of Control*

- 1 Provisions and safeguards of the 1930 Act
- 2 Difficulties in interpretation
- 3 Statistical data
- 4 Procedure in Southern Rhodesia and Northern Ireland
- 5 Possible changes in the 1930 Act

Temporary treatment is the procedure by which patients who have no volition, that is to say who are incapable of expressing themselves as willing or unwilling to receive treatment, may be detained for a limited time without certification as persons of unsound mind. This procedure is not followed in Scotland, but applies to England and Wales only.

Before the passing of the Mental Treatment Act, 1930, a poor person resident in England or Wales could not, in general, receive treatment for mental illness until he had

been certified as of unsound mind and sent to a mental hospital under a reception order made by a justice. The main purpose of the Act of 1930 was to remedy this state of affairs and to give effect to the recommendation of the Royal Commission which, when reporting in 1926, had urged that certification should be the last resort and not the necessary preliminary to treatment. Accordingly the Act not only enabled local authorities to make provision for out-patient and voluntary in-patient treatment for poor persons but also, by section 5, required them to take such steps as they considered necessary to provide and maintain suitable accommodation for the reception of temporary patients.

### 1. Provisions and Safeguards of the 1930 Act

Treatment under the provisions of section 5 is obtainable on written application made, if possible, by the husband or wife, or by a relative of the person to whom it relates, accompanied by a recommendation signed by two doctors, of whom one should, if practicable, be the usual medical attendant of the patient, and the other a doctor approved for the purpose of making recommendations under the section by the Minister of Health. Treatment is limited, in the first instance, to six months, but if it is anticipated that the patient will not recover within the period of six months, though his early recovery thereafter appears reasonably probable, it may be extended on application duly made not more than one month nor less than 14 days before the expiration of the current period of treatment, for further periods of such lengths not exceeding three months as may be directed by the Board of Control, provided that such further periods shall not exceed six months in all.

In order to safeguard the patient against improper

### THE MENTALLY ABNORMAL CRIMINAL

*Continued from page 58*

and the Home Secretary has power to transfer the prisoner to a mental hospital. The most serious cases are usually detained in the State Mental Hospital at Broadmoor, Berkshire.

#### 8. Minor Forms of Mental Abnormality

A part of certain prisons is used as an observation and treatment centre for prisoners who are suffering from lesser forms of mental abnormality, and psychotherapists are engaged to treat cases susceptible to this form of treatment. If modern methods of diagnosis and treatment are not available the prisoner can be sent to a mental hospital or clinic for the purpose. The Prison Commissioners have accepted the principle of establishing on colony lines a special institution under their administration for this class of offender. But difficulties due to the Second World War have delayed its inception.

Offenders suffering from mental abnormality are frequently remanded to prison for medical examination and report. The Criminal Justice Act 1948 empowers the Court also to remand an offender on bail for a first period of three weeks, to enable a

medical examination and report to be made. A person remanded on bail may be received for this purpose into an institution within the meaning of the Mental Treatment Act 1930 (i.e., a mental hospital or other premises maintained by a Local Authority for the purposes of this Act), a registered hospital or licensed house, or into an institution for mentally defective persons within the meanings of the Mental Deficiency Acts.

When the court is satisfied on expert medical evidence that the mental condition of the offender requires and may be susceptible to treatment, but is not such as to justify his being certified as a person of unsound mind under the Lunacy Act 1890, or as a defective under the Mental Deficiency Act 1913, the Criminal Justice Act allows a court to add to a probation order a requirement that the offender shall undergo medical treatment for a period not extending beyond twelve months, with a view to the improvement of the offender's mental condition. It is believed that such treatment, if commenced early in an offender's career, may have lasting benefit and tend to reduce the amount of crime committed by mentally abnormal persons.

reception or detention the section provides for him being visited within one month of his reception by two members of the hospital management committee and that, if he becomes capable of expressing himself as willing or unwilling to receive treatment, he shall not thereafter be detained for more than 28 days unless in the meantime he has again become incapable of expressing himself. Power to discharge is vested in the same persons and bodies as in the case of a certified patient with the added safeguard that the Board of Control may at any time order that the patient shall be discharged or that steps shall be taken to obtain a reception order for his detention as a person of unsound mind.

## 2. Difficulties in Interpretation

Section 5 was designed to provide treatment for the confusional type of case, of which it was estimated that there was a considerable number, and in particular for puerperal cases, many of whom fall within its scope. It appears to have been thought that continuance of treatment would readily be secured by regrading patients as voluntary patients if they recovered volition during their period of temporary treatment. From the outset, however, difficulty arose as to the interpretation of subsection (12), which provides that

if a person who has been received as a temporary patient becomes capable of expressing himself as willing or unwilling to receive treatment he shall not thereafter be detained for more than twenty-eight days unless in the meantime he has again become incapable of so expressing himself.

Doctors were naturally prone to regard the words "capable of expressing himself" as indicating the expression of a rational wish which was in conformity with the interests of the patient. That such an interpretation was not the intention of Parliament was clear from a passage from the speech of the Government spokesman during the debate in the House of Lords which ran as follows:

No attempt should be made to construe 'volition' as meaning rational volition. Therefore even if the wish is irrational or is contrary to the best interests of the patient, if he expresses willingness or unwillingness he cannot properly be regarded as without volition.

This interpretation of subsection (12), which the Board of Control felt bound to give effect to, imposed serious burdens not only upon medical superintendents in relation to treatment but also raised difficult problems for the bodies and persons charged with the statutory visitation of temporary patients, within one month of their reception, under subsection (9). As regards the latter it meant, in strictness, that if upon visitation the patient, however confused he might be, expressed a wish to go home, the statutory visitor was under a duty to report to the Board of Control that it was not proper that he should continue to be detained under care and treatment. As a result of these difficulties the section soon came to be regarded by many medical superintendents as unsatisfactory and too complicated to be worthy of operation.

## 3. Statistical Data

Reviewing the position in their report for 1935 the Board of Control stated that, whereas the number of temporary patients admitted to public mental hospitals in 1931 represented 1.8 per cent of the total direct admissions, that figure had by 1935, as a result of special efforts made by the Board

and by Local Authorities, risen to 5.2 per cent; they commented on the fact that this latter figure was little more than half the proportion of temporary admissions to private institutions and expressed the view that experience over the five years since the coming into operation of the Act confirmed the estimate of its framers that the proportion of admissions falling within the scope of the section was not likely to exceed 15 per cent. It appears from a study of the relevant section of the Board's 1935 Report that even at that date they were of opinion that some simplification of the provisions of the section was indicated as soon as a favourable opportunity occurred, and that this might take the form of a modification of the twenty-eight-days rule, which necessitates regrading and fresh formalities if the patient's condition changes and there is a return of volition.

The figure of 5.2 per cent recorded in the Board of Control's report for 1935 was exceeded only in two subsequent years, namely in 1936 when it was 5.3 per cent and in 1938, in which year it rose to 5.5 per cent. From 1938 to 1946 it hovered around 4 per cent but the figure for 1947 descended to 3.5 per cent. It seems significant also that the corresponding figure for temporary admissions to private institutions and single care (types of care catering for the wealthier sections of the community) have fallen from 8.5 per cent in 1935 to 2.9 per cent in 1947. Incidentally, it may be of interest to record here that, in relation to the total direct admissions to public mental hospitals, the percentage of certified patients, which in 1931 stood at 91.1 per cent, had by the end of 1947 decreased to 42 per cent, while the corresponding percentage of voluntary admissions to such hospitals in 1947 attained a new high average at 54.5 per cent.

It seems clear from the figures quoted above, that the existing provisions for temporary treatment, contained in section 5, have been found so complicated and difficult of operation that they have had a deterrent effect upon those who contemplated availing themselves of them. Drastic alteration seems necessary both as regards the provision relating to initial reception as a temporary patient and in order to do away with the twenty-eight-days rule, which necessitates regrading and fresh formalities on return of volition. What form should the alteration take?

## 4. Procedure in Southern Rhodesia and Northern Ireland

The provisions of section 5 have been reproduced, with or without modification in detail, in various Dominion and Colonial enactments, and the relevant provisions of two of these, the Southern Rhodesian (Mental Disorders) Act, 1936, and the Mental Health Act (Northern Ireland), 1948, appear to be worthy of consideration.

*Southern Rhodesia.*—Sections 44 to 46 of the Southern Rhodesian Act afford temporary treatment, without the intervention of a judicial authority, to

a person who is suffering from mental disorder (whether he is or is not capable of expressing volition) and is likely to benefit by temporary treatment, but is also unfit on account of his mental state to be received and maintained as a voluntary patient.

The provisions relating to applications for treatment, visitation after reception, period of treatment and discharge, follow closely the wording of the English Mental Treatment Act except that the person who made the original application may, at any time, order the patient's discharge. Section 74

also provides a general safeguard enabling the patient to call the Courts to his aid.

The effect of these sections seems to be to provide for temporary treatment of resistive as well as of non-volitional patients; thus patients who, though volitional in the sense that they express refusal of treatment, are, in the judgement of the two doctors making the recommendation, without insight into their mental condition and unaware of their need for treatment, can be detained for a period not exceeding, with any extensions granted by the prescribed Authority, 12 months in all.

There is much to be said in favour of these provisions which, it will be observed, abolish the (twenty-eight-days) rule in the English Act requiring the regrading of the patient as a voluntary patient within 28 days after recovery of volition, and enable the doctor in charge of the patient either to continue to detain the patient for the current period of treatment if he is not satisfied that recovery of volition is likely to be permanent or, if at any time during the current period he believes that recovery of volition is likely to be permanent, to regrade the patient on a voluntary basis. A further advantage, from the medical point of view, is that by affording temporary treatment to resistive patients whose refusal of treatment is due to lack of insight into their mental condition, the Rhodesian Act recognizes such refusal and also any protests during treatment as irrational, and permits treatment to be continued unhindered.

*Northern Ireland.*—The provisions of the Northern Ireland Act are somewhat revolutionary, their effect being that persons admitted to mental hospitals will be in two groups only. The first group consists of voluntary patients who appreciate their need for treatment and apply to obtain it, the second group of temporary patients.

Section 7 of this Act makes provision for the reception into a mental hospital, on a written application duly made in accordance with the provisions of the section, of a person who is suffering from mental illness and is unfit on account of his mental state to be received (or to continue) as a voluntary patient, or of a person who is an addict, as a temporary patient. The application must be accompanied by a recommendation in the prescribed form signed by a duly qualified medical practitioner and specifying the grounds on which he bases his recommendation. Treatment in the temporary category is for an initial period of one year which may from time to time be extended for further periods of such length, not exceeding six months, as may be specified in directions given by the Ministry of Health and Local Government, provided, however, that the total period of treatment as a temporary patient shall not in any case exceed two years from the date of the patient's first admission as such. When, however, the patient is, at the completion of the two years, undergoing special treatment and the Ministry

is satisfied that the patient's recovery is probable on the completion of that special treatment, the Ministry may authorize an extension of the period of special treatment beyond the two years for the purpose of the completion of the special treatment. Section 9 provides that when it is no longer proper to retain a mentally ill person as a temporary patient steps may be taken to have him certified, by a judicial authority, as a person of unsound mind.

Subsection (3) of section 6 of the same Act makes provision for the taking of steps to deal with a voluntary patient as a temporary patient if the medical superintendent is satisfied that the patient is, by reason of a change in his mental state, unable to appreciate his status as a voluntary patient and has remained in that condition for a period of 28 days.

### 5. Possible Changes in the 1930 Act

The scheme of the Northern Ireland Act attains in full measure the objective put forward by the Royal Commission that certification should be the last resort and not the necessary preliminary to treatment and, in that respect, its provisions are most attractive. The British Parliament, however, has always been assiduous to preserve the liberty of the subject and to provide strong safeguards when mentally ill persons are detained. Would it look with favour upon, firstly, the signing of a recommendation for temporary treatment by only *one* medical practitioner (who need not apparently be specially qualified in the diagnosis and treatment of mental disorders), and secondly, the fixing of the initial period of temporary treatment at *one year* with further six-monthly extensions to a full period of two years?

As regards the first question, the Board of Control has always taken the view that there is no legal objection to the second signatory of the existing form of recommendation (who must be a registered medical practitioner approved by the Minister of Health for the purpose of making recommendations under section 5) being a senior medical officer of the hospital into which the patient is to be received. If the second signatory is either such a medical officer or a consultant whose services are available free of charge under the National Health Act, 1946, the requirement that the recommendation must be signed by two doctors should not present difficulty either upon the ground of expense or otherwise. It seems possible, therefore, that Parliament may think it desirable to preserve the existing requirement that the recommendation shall be signed by two doctors.

As regards the total period of temporary treatment to be permitted, perhaps an extension to eighteen months in all would afford a reasonable compromise between medical and legal views.

## ASPECTS OF THE PSYCHOPATHOLOGY OF OLD AGE

### Revealed in Witchcraft Cases of the Sixteenth and Seventeenth Centuries

SONA ROSA BURSTEIN M.A.

*Wellcome Historical Medical Museum, London*

The hazards of senescence belong in large proportion essentially to the sphere of mental health. This appears now to be the considered verdict of both medicine and science. In 1948, problems of old age for the first time formed a distinct feature of the programmes of the British Medical Association and the British Association for the Advancement of Science, at their annual meetings in June and September respectively. At both meetings, papers and discussions emphasized the social and psychological disorientation which threatens the ageing individual in the pace and stress of contemporary living; at the British Medical Association meeting, the discussion on old age was included, significantly, in the section of Neurology and Psychiatry.<sup>84a, b</sup>

Old people are much in today's news. The increased longevity which is the proud achievement of improved medicine and hygiene has led to an unprecedented increase in the numerical proportion of the old-age group of the population. Medicine, science, changing birth-rate, war and migration have together created an imbalance, which population trends threaten to intensify. Consciousness of the effect of the strain of contemporary life on the aged is forced upon us by their very numbers. It was pointed out some time ago by Lord Amulree that many old people were suffering from underfeeding, not because of inadequate rations but because they could not stand in queues and carry home heavy parcels.<sup>94</sup> The implication is that much of the chronic sickness of the aged is due to current social conditions in the community. The truth seems to lie in the truism that old age is not a new thing, and that problems of adjustment to old age are as old as mankind.

Four hundred years ago old women were the news—bad news, dire news! An angry verbal passage-at-arms with a shrill-voiced hag—and a man would go home to frighten himself nearly or quite to death at the first aches or cramps that might come to him. The very sight of an old crone mumbling to herself could send children into convulsions and rouse a storm of mob excitement. *Wonderfull news from the North . . . ; Strange and terrible news from Salisbury . . . ; The most true and wonderful narration . . . ; A detection of damnable driftes . . .* with such headlines the pamphleteers, the reporters of the time, spread the tidings of witches brought to trial and doom, and so fostered suspicion and further convictions.

It is not the purpose of this paper to examine the long and complex history of belief in witchcraft, which reached its height in the 16th and 17th centuries. The antiquity of the worship which is at the basis of the witch-cult has been amply set forth by Margaret Murray<sup>55</sup> and others. Much literature and theory have been devoted to interpreting the records in the light of the belief of Montague Summers<sup>57</sup> or the scepticism of the late Henry Charles Lea,<sup>53</sup> authorities to whose industry and scholarship every student of witch-beliefs owes so much. Moreover, it is certainly proved beyond argument that, from the earliest antiquity to modern times, accusations, prosecution and punishment for witchcraft have fallen on people of both sexes and all ages. In the list of those executed for witchcraft in the town of Würzburg, for example, in the years 1627 to 1629, in which 151 names are recorded, there are as many men as women, and no less than thirty children.<sup>51 58</sup>

Nevertheless, at the height of the witch-trials of the 16th and 17th centuries, the vast majority of the accused were old women. Of this we have overwhelming evidence in the works of contemporary writers—philosophers, doctors, and jurists, both English and Continental; in the reports of indictments and trials; in contemporary pamphlets and ballads; and in folk-memory expressed in song, legend and literature at a later date. There is an undoubted challenge to those concerned with mental and social welfare in the question why, for two and a half centuries, suspicion of, and prosecution for, witchcraft constituted a major hazard of female senescence.

#### Evidence of Contemporary English and Scottish Writers

Reginald Scot, summing up the sceptic's case against witchcraft, says that witches "be commonly old, lame, bleare-eyed, pale, fowle and full of wrinkles . . . in whose drousie minds the divell hath gotten a fine seat; . . . leane and deformed, showing melancholie in their faces . . . doting, scolds, mad, divellish." Towards the end of the book he gives his definition of witchcraft as "in truth a cosening art . . . a supernaturall worke, contrived between a corporall old woman and a spirituall divell."<sup>22</sup>

A hundred years later, we find Joseph Glanvill setting forth the case for belief in witchcraft and persecution of witches with passionate conviction and all the sober, reasoned argument of the 17th century thinker. Yet even he has to find some way of answering the objection that "'Tis very improbable that the devil who is a wise and mighty spirit would be at the beck of a poor hag, and have so little to do as to attend the errands and impotent lusts of a silly old woman," and the fact that the "accused persons are usually crazy and imaginative old women."<sup>18</sup> William Perkins, too, in his *Discourse on the damned art of witchcraft*, indignantly rejects the expressed view that witches were "merely aged persons of weake braines and troubled with abundance of melancholie."<sup>20</sup>

Notestein quotes an English newspaper, *The Moderate Intelligencer* of September 1645, which has an editorial commenting on a current case, thus:

But whence is it that Devils should choose to be conversant with silly old women that know not their right hands from their left, is a great wonder . . . they will meddle with none but poore old women: as appears by what we have received this day from Bury . . . Divers are condemned and some executed and more like to be. Life is precious and there is need of great inquisition before it is taken away.<sup>56</sup>

FIG. 1. AN EARLY ATTACK ON WITCHMONGERS

Title-page of Reginald Scot's *Discovery of witchcraft*, 1651 edition.  
 (From a copy in the library of the Wellcome Historical Medical  
 Museum)

As late as 1668, when scepticism was well advanced, William Drage, "practitioner in physick", gives the following panacea for diseases caused by witchcraft:

Punish the witch, threaten to hang her if she help not the sick, scratch and fetch blood. When she is cast into prison, the sick are some time delivered, some time he or she (they are most females, most old women, and most poor) must transfer the disease to other persons, sometimes to a dog, or horse, or cow. Threaten her and beat her to remove it.<sup>14</sup>

John Gaule, vicar of Great Staughton, a contemporary resident in East Anglia at the time of Matthew Hopkins' great witch-drive in that region, and a credible witness in that he was himself a believer in witchcraft, writes: "Every old woman with a wrinkled face, a furred brow, a hairy lip, a squint eye, a squeaking voice, or a scolding tongue, a skull-cap on her head, a spindle in her hand, a Dog or Cat by her side, is not only suspected but pronounced for a witch."<sup>15</sup> There is no change here from Archbishop Harsnett's description, nearly fifty years earlier, of the accepted idea of a witch:

... an old weather-beaten croane, having her chinne and her knees meeting for age, walking like a bow leaning on a

shaft, hollow-eyed, untoothed, furrowed on her face, having her lips trembling with the palsie, going mumbling in the streets; one that hath forgotten her *pater noster* and yet hath a shrewd tongue in her head to call a drab a drab.<sup>16</sup>

Master Thomas Potts, who acted as clerk to the court in the notorious case of the Lancashire witches, has left us a faithful and accurate chronicle of what took place at the trial, with almost photographic detail of the "examinates". Describing the cross-examination of one of the principals accused in the case, Anne Chattox, "a very old, withered, spent and decrepit creature, her sight almost gone," he makes this significant remark: "... for the wrinkles of an old wives face is good evidence to the Jurie against a witch. And how often will the common people say *Her eyes are sunke in her head, God blesse us from her.*"<sup>17</sup>

Roger North, a distinguished lawyer who was at Exeter in 1682 when a famous witch trial occurred, wrote in a letter: "... They were the most old, miserable, decrepit creatures ... a painter would have chosen them out of the whole country for figures of that kind to have drawn from." Elsewhere he gives a vivid account of the popular excitement: "The women were very old, decrepit and impotent and were brought to the assizes with as much noise and fury of the rabble against them as could be shewed on any occasion. The story of their acts was in everyone's mouth ... all which the country believed and accordingly persecuted the wretched old creatures."<sup>18</sup>

Sir George Mackenzie, acting as counsel for the defence (permitted in Scottish procedure only) in a witchcraft case between 1660 and 1670, opens the final summing-up of his argument with these words: "Consider how much fancy does influence ordinar Judges in the trial of this crime, for none now labour under any extraordinary Disease but it is instantly said to come by Witchcraft and then the next old, deformed or envyed woman is presently charged with it."<sup>19</sup>

Blackstone,<sup>20</sup> referring to the laws of Henry VIII and James I, which made the practice of witchcraft a felony "without benefit of clergy" and punishable by death, says: "These acts continued in force till lately, to the terror of all antient females in the kingdom, and many poor wretches were sacrificed thereby to the prejudice of their neighbours and their own illusions."

#### Evidence of Contemporary Continental Writers

Continental writers are, if anything, even more explicit in attributing the witch-character to old women, whether in accusation, defence or rationalization. In 1550, the Italian physician and mathematician, Jerome Cardan, published a book, *De subtilitate*, in which he regarded witchcraft as an illusion engendered by poverty, hardship and lack of nourishment, but founded on some reality. He says:

What are we to think of those called *lamiae* or vulgarly *strigae*? They are miserable old women, beggars, existing in the valleys on chestnuts and field herbs and, but for a little milk, would starve. They are emaciated, deformed, with prying eyes, pallid, showing in their faces black bile and melancholy. They are taciturn, stupid and differ little from those called demoniacs. They are fixed in their opinions and so stubborn that, if one regard only what they so boldly repeat that is impossible, we should regard it as true.<sup>21</sup>

Cardan's countryman, Arnaldus Albertinus, in a tract published in 1572 asserting the existence of witchcraft and the guilt of witches, says that the latter are "mostly old

women who can find no lovers and become *strigae*, when they commit unspeakable things."<sup>11</sup>

The great pioneer in regarding the mentality and behaviour of old women—which exposed them to accusations of witchcraft—as manifestations of mental illness was Johann Weyer, known also as Wier or Wierus. In his book, *De praestigiis daemonum*, published in 1563, while proclaiming his own orthodox belief in witchcraft, he asserted the folly of attributing supernatural powers to old women, and denounced the cruelty of their persecution. In his introduction he says, "Witches are poor, ignorant creatures, old and powerless, who without instruction imagine themselves, in their desperation and degradation, to be the cause of the evils which God sends to man and beast." In the dedication he recapitulates with approbation the opinions of his patron, the Duke of Cleves, that old women, misled by devils, imagine that they cause the evils which happen to others whom they desire to harm. In accordance with this view, in the Duke's domains foolish old women were not put to death, and were punished only if there was a proved case of poisoning.<sup>26</sup> In the introduction to his second book, *De lamiis*, Weyer congratulates himself on the success of his efforts to diminish the slaughter of innocent old women, but as the tyrants have renewed their persecutions, he proposes to put his opinions into condensed form and to prevent the shedding of innocent blood.<sup>27</sup> His constant use of the diminutive—*mulierculae*, *aniculae*, *vetulae*—, in referring to the old women he defends, is worthy of note.

Frommann, writing in 1675 on "fascination", the evil eye and attendant phenomena, subscribes to the view that witchcraft is mostly practised by uneducated old women ("... indoctis magis quam doctis senibus magis quam juvenibus, mulieribus quam viris probari miretur nemo").<sup>28</sup> An occurrence quoted by Westphal in a book called *Pathologia daemoniaca*, published in Leipzig in 1707, indicates that the tradition of Weyer had taken some hold in the medical world, even in Germany, the stronghold of the belief in witches. The story is of an old woman who, in 1674, a century after Weyer was writing, confessed to congress with an incubus. She was handed over for medical examination; this in itself marks an enormous advance. Dr. Michael Ettmüller, in a long opinion given with much detail of symptoms, pronounced her insane and declared her intercourse with demons imaginary, and her "progeny" nothing but faecal discharges after severe constipation. The Medical Faculty of Leipzig concurred in this opinion and she was saved from the stake.<sup>29</sup> <sup>32</sup> The outstanding name in the conflict against persecutions for witchcraft in 17th century Germany is that of Christian Thomasius, of whom Frederick the Great said that he "vindicated the right of women to grow old in safety."<sup>31</sup>

In England, the chief protagonists for the defence of old women against witchcraft persecution were amateurs and laymen. Reginald Scot was a country squire, who with equal ability and enthusiasm devoted his leisure to writing on his two paramount interests—the defence of witches and the growing of hops. His evidence for the former is mostly drawn from the life and beliefs of the people. Continental witch-belief was far withdrawn from popular superstition and vulgar rumour. It was claimed as an exact science based on observations by able and enlightened men, and its arguments were founded on the scholarship

of generations. In the revised Criminal Code of Saxony of 1572, the opinions of Johann Weyer (*Wieri rationes*) in relation to witchcraft are derided as worthless because he was only a doctor, lacking the scholarship and precision of the jurist.<sup>45</sup> It is the very difference in the character of English and Continental witch-belief that makes the similarity of the witch-personnel in both cases of such vital significance.

#### Characteristic Senile Behaviour of Suspected "Witches"

There have not been wanting others than Weyer, with less conscious purpose, to point out, by explicit statement or by implication, that many of the old women involved were either crazed or doting. The characteristics of mumbling senility were undoubtedly taken as evidence. "None ever talked to themselves that were not witches," said a common witch-pricker.<sup>40a</sup> Potts describes old Mother Chattox with "her lippes ever chattering and walking; but no man knew what."<sup>45</sup> A manuscript of the time of James I deals with: "Circumstances to be considered in the cause of [Joane Harvy] the mayde of Hookham... for scratching of an old witch there [Mother Francis], now deade." In a marginal note, Mother Francis is described as "old and crazed and hurte by a fall." From the text we learn that she was aged about eighty and that the fall was out of bed—a danger well known to those who have charge of the infirm aged.<sup>1</sup>

Not least evident in the narratives is that type of senile psychotic behaviour arising from lack of comprehension of immediate reality or danger. Eighty-year-old Temperance Lloyd, we are told in a contemporary pamphlet,<sup>74</sup> went to the gallows "all the way eating and was seemingly unconcerned." Several accounts of the last witch-burning in Scotland, as late as 1722, tell of how the accused, described variously as "demented" and "a fatuous old woman", was quite unconscious of the stir about her as she was led to the stake and stretched out her hands to the blaze, chattering her pleasure at "the bonnie fire."<sup>42</sup>

The typical, irritable, discontented old woman, the village scold, with "a shrewd tongue in her head to call a drab a drab", seems generally to have been careless enough of her own danger. Over and over again it is this loud, aggressive behaviour which brings the woman into trouble. Elizabeth Sawyer, the witch of Edmonton, who was the very type depicted by popular belief "with body crooked and deformed, even bending together", confessed to the Rev. Henry Goodcole who visited her constantly in Newgate until her execution, that her "tongue... by cursing, blaspheming and imprecating... was the occasioning cause of the Divil's access unto her."<sup>33</sup>

In the case of the notorious fraud of the "Boy of Bilson", exposed by Bishop Morton in 1620, the boy, William Perry, being asked why he had accused this particular old woman of causing his pretended "possession", replied that "she being known to him and of a *scolding humour*, he fixt it on her." Arthur Wilson, James the First's chronicler, who recounts the story, says that the old woman "had no good reputation among the Neighbours, being of a tetric and froward temper incident to old age." The good bishop seems to have been well ahead of his time in assessment of both senile psychology and juvenile delinquency, for he took the young exhibitionist into his own home and educated

him: "Thus", says Wilson, "did the Bishop preserve an innocent old woman condemned by the Law to die . . . and convert a wicked boy whom afterwards he bound Apprentice and proved a good man."<sup>28</sup>

A witchcraft trial which took place in Württemberg early in the 17th century (1615-21), casts considerable light on the communal psychological situation. This was the case of the mother of the famous Johann Kepler. The "Keplerin", as she was called, deserted by a thriftless husband, soured and embittered by misfortune, made morose and eccentric by solitude, was accused of witchcraft by a neighbour whom she had insulted. Her astronomer son, defending her, was under no illusion as to her temper. He described her as "small, thin, swarthy, sharp-tongued, quarrelsome, of evil mind," and a disturber of the whole community. In a letter he writes:

Rumour is an evil than which none is swifter; for this suspicion spread at once among highly superstitious folk, since they based their argument on the seventy years' age of my mother and on several of the faults with which my mother is burdened, which are lying, prying, violent anger, cursing, persistence in complaints, which vices at that age are very common . . .<sup>30</sup>

Giffard<sup>17</sup> sketches a deft picture of how a witchcraft accusation may arise from local quarrels:

Some woman doth fall out bitterly with her neighbour: there followeth some great hurt . . . There is a suspicion conceived. Within a few years she is in some jarre with an other. This is noted of all. Great fame is spread of the matter. Mother W. is a witch . . . Well, Mother W. doth begin to be very odious and terrible unto many, her neighbours dare say nothing but yet in their hearts they wish she were hanged. Shortly after an other falleth sicke and doth pine . . . Everyone sayth now that Mother W. is a witch in deede . . . It is out of all doubt.

#### Contemporary Interpretations of the Behaviour of Supposed Witches

Reginald Scot prefixes his *Discoverie of witchcraft* with an epistle to his kinsman, Sir Thomas Scot, in which he covers a whole range of senile psychotic behaviour and makes some acute observations on cause and effect. He pleads,

. . . that lawfull favour and Christian compassion be rather used towards these poore soules, than rigour and extremitie. Because they, which are commonlie accused of witchcraft, are the least sufficient of all others to speake for themselves; as having the most base and simple education of all others; the extremitie of their age giving them leave to dote, their povertie to beg, their wrongs to chide and threaten (*as being void of any other waie of revenge*), their humor melancholicall to be full of imaginations, from whence chiefly proceedeth the vanities of their confessions: as that they can transform themselves and others into apes, owles, asses, dogs, cats &c.; that they can flie through the aire, kill children with charms, hinder the coming of butter &c.

The confessions of the accused have been taken variously as proving the reality of their guilt or as the ramblings of insanity, shaped by current belief. Most of the confessions were certainly made under duress, whether of the rack of the Continental courts, the "boots" and "pennywinkis" (a kind of thumb-screw) of the less ceremonial torture of Scotland, or in England, where official torture was not permitted, the refinements of the witch-hunter's third-degree methods—"floating", maintaining for hours a strained and painful position, keeping from sleep for many nights and days, "walking between two" up and down a room to the limits of endurance of feet and heart and brain. Of the confessions made without apparent coercion, it has to be

FIG. 2. TESTING A SUSPECTED WITCH BY "FLOATING"

Witches Apprehended, Examined and Executed, for notable villanies by them committed both by Land and Water.

With a strange and most true triall how to know whether a woman be a Witch or not.

Printed at London for Edward Marchant, and are to be sold at his shop ouer against the Crosse in Pauls Church-yard. 1613.

Title-page of an account of the trial of Mother Hutton and her daughter Mary at Bedford in 1612. (From a contemporary pamphlet<sup>10</sup> in the Bodleian Library, Oxford)

remembered that many were made in the hope of gaining the mercy of the courts, were it only the mercy of strangling before burning. Further, most of the accused fully believed in the existence of the powers attributed to them and we find not a few cases of women asking sincerely if it were possible they could have committed these grievous sins without knowing.<sup>58</sup> Mary Smith, in 1616, made a full confession for her soul's salvation and died on the gallows in great penitence and piety, fully believing herself to have been a witch.<sup>6</sup> Nevertheless, there was a large number of spontaneous confessions as surprising and puzzling to contemporary observers as to later inquirers. North observed of the women at the Exeter trial: "The evidence against them was very full, but their own confessions exceeded it. They appeared not only weary of their lives but to have a great deal of skill to convict themselves."<sup>33</sup>

The "humor melancholicall" which, according to Scot,<sup>22</sup> makes old women "full of imaginations", is a theme to which he constantly reverts. Two of the chapter-headings of Book III of the *Discovery* run: (Chap. X) *How melancholie abuseth old women and of the effects thereof, by sundrie examples*, and (Chap. XI) *The strange and divers effects of melancholie and how the same humour abounding in witches, or rather old women, filleth them full of marvellous imaginations and that their confessions are not to be credited*. "Melancholy" is a common diagnosis of the time. A 16th century manuscript in the British Museum, written by an unnamed Kentish man, who had certainly read and digested the works of Weyer and Scot and other sympathetic writers, repeats this second chapter-heading almost verbatim and adds: "If our witches fantasies were not corrupted, nor their wills confounded with this humor, they would not so voluntarilie and readilie confess that which calleth their life in question."<sup>22</sup>

Webster, exposing the fallacies of supposed witchcraft, wrote of "divers persons under a passive delusion of Melancholy and Fancy."<sup>25</sup> Burton, in the *Anatomy of melancholy*, says: "This natural infirmity is most eminent in old women, and such as are poor, solitary, live in most base esteem and beggary or such as are witches; insomuch that Wierus, Baptista Porta, Ulricus Molitor, Edwicus, do refer all that witches are said to do, to imagination alone, and this humour of melancholy."<sup>12</sup>

Arthur Wilson (1653) saw nothing in the women condemned at Chelmsford "other than poor mellencholie . . . ill-dieted, atrabilious constitutions, whose fancies working by grosse fumes and vapors might make the imagination ready to take any impression."<sup>28</sup>

Weyer, the doctor, would have the "evil deeds confessed" minutely inquired into, as to the validity of the alleged means and effects and also

as to whether there be any melancholy or mental disorder . . . In this business there is much of turbulence, of suspicion, of malignity; much is confusedly disseminated about others. The confessions of old women deluded by demons are accepted and the judge who lends a facile ear to accusations and confessions will find himself deluded and involved in an inextricable labyrinth . . . How can faith be reposed in confessions made by those not in their right senses? And if these old women confess lies, it vitiates the whole confession.<sup>27</sup>

Elsewhere referring to the trials of Job and the madness of Nebuchadnezzar, Weyer continues:

It is fortunate that they are not among us today, for if they were hereabouts, some old woman would shoulder the responsibility for their distress, and the brains of these old women

are so inflamed that, under torture they would confess to having caused all these terrors.<sup>25</sup>

It is interesting to note that, while modern scholarship piles up research and argument to prove that the attribution of the witch-character to women, of whatever age, derives from ancient cults of mother-goddess and earth-goddess, to those who lived in the centuries of witch-belief it was something inherent in female nature. Whether seen in the shadow of the passionate misogyny of the *Malleus maleficarum*<sup>24</sup>, that 15th century vade-mecum of all witch-hunters, or in the light of Weyer's healing kindness, woman was weak, excitable, liable to deception and fit for diabolic illusions.<sup>24</sup> Scot quotes from Leonhardus Vairus: "And therefore, he sayth . . . women are oftener found to be witches than men: For (sayth he) they have such an unbridled force of fury and concupiscence generally . . . and of all other women, leane, hollow-eyed, old, beetle-browed women (sayth he) are the most infectious."<sup>22</sup>

As early as 1550 Cardan attributed the witch-behaviour of old women to want, hunger and hardship. Weyer constantly refers to their poverty. The dependence on charity is specially notable in the English narratives. Webster in 1677 laughs to scorn the idea "that the Devil should carry an old Witch into the air into foreign regions, that can hardly crawl with a staff, to dancing and banqueting, and yet to return with an empty belly and the next day be forced, like old Dembdike or Elizabeth Sothernes," (i.e. the Lancashire witches) ". . . to go a-begging with the sour-milk can."<sup>25</sup>

The pattern of the curse which followed the refusal of alms is endlessly repeated in the narratives. Such is the story told by Glanvill<sup>18</sup> of Julian Cox and the maid-servant said to have been bewitched by her. Says Scot in his introductory epistle:

May it please you to waie what accusations and crimes they laie to their charge, namelie: She was at my house of late, she would have had a pot of milke, she departed in a chafe because she had it not, she railed, she cursed, she mumbled and whispered, and finally she said she would be even with me: and soon after, my child, my cow, my sow, or my pullet died, or was strangellie taken . . .

In a pamphlet published in 1687,<sup>8</sup> giving an account five years after the event of the trial described by North, we read that the judge ". . . in his charge to the jury gave his opinion that these three poor women (as he supposed) were weary of their lives, and that he thought it proper for them to be carried to the Parish from whence they came, and that the Parish should be charged with their maintenance; for he thought their oppressing Poverty had constrained them to wish for death."

The authors of the play *The witch of Edmonton*,<sup>21</sup> written in 1658, put a shrewd summing-up of the situation into the mouth of Elizabeth Sawyer:

Why should the envious world  
Throw their scandalous malice upon me,  
'Cause I am poore, deform'd and ignorant  
And, like a bow, buckled and bent together?  
Must I for that be made a common sink  
For all the filth and rubbish of Men's tongues  
To fall and run into? Some call me Witch;  
And, being ignorant myself, they go  
About to teach me how to be one; urging  
That my bad tongue (by their own malice made so)  
Forespeaks their Cattle, doth bewitch their Corn,

Themselves, their Servants, and their Babes at nurse.  
Thus they enforce upon me; and in part  
Make me to credit it . . .

Act II, Scene I

### Modern Medical Interpretations

Some individuals living at the time, with every excuse of training and social pressure to regard these old women as enemies of society, could make thoughtful interpretation of the behaviour of both persecutor and persecuted. A Johann Weyer could blaze a trail for the modern alienist. Yet doctors of later times have tended to relegate the whole matter of witchcraft to the antiquarian and the folk-lorist, as if the very type and character of the witch-suspect disappeared with the last recorded burning or hanging. "The undiscovered country of witch pathology," says Kittredge, "awaits its trained explorer."<sup>61</sup> And Zilboorg makes the reproach: "As the fires of the Inquisition stopped burning, so did the fires of compassionate medical curiosity."<sup>62</sup>

Nevertheless, there is not complete silence. Alienists of the later 19th century such as Hack Tuke and Maudsley<sup>63</sup> make reference, albeit briefly, to the witchcraft records as of some value in their work with the insane. Tuke declares that "it is impossible to read the narratives of some of the unfortunate hags who were put to death for witchcraft, without recognizing the well-marked features of the victims of cerebral disorder."<sup>78</sup>

In Germany, Kirchhoff, after a careful study of the original records of the witch trials, stated that he often found the reported answers and conversations exactly like those familiar to him in asylums for the insane. He names some forms of mental disease (notably dementia senilis and epilepsy) which, he considers, constantly and unmistakably appear among those who suffered trial for witchcraft.<sup>66</sup> Snell also made detailed investigations into psychological aspects of the witch trials, with a view to application to psychiatric studies.<sup>74 75</sup> He points out that the mentally sick person may be the accused or the accuser, and mentions that self-accusation of serious crimes is a recognized symptom of mental disorder.

A series of articles<sup>70a, b, c</sup> on the "State of Society, Past and Present, in Relation to Criminal Psychology" appeared in 1881-3, from the pen of David Nicolson, deputy-superintendent of Broadmoor Criminal Lunatic Asylum. This contribution, sadly isolated in outlook and treatment of its subject, presents the suspected witches in the setting of their daily life and neighbourhood, and attempts an assessment of the social implications of the persecutions. As a pioneering effort it is worthy of lengthy quotation:

In the study of criminal trials, such as those with which we are at present concerned, we are brought face to face with the social phenomena of the time being in all their bearings and, in the cases here given, there will always be found something of psychological interest, either as regards the domestic and other concerns of the community or as regards individuals prosecuted or individuals prosecuting. The evidence, where given, will throw light upon the different ways that people had of looking at their relationships and of interpreting the circumstances taking place around them.

Sometimes the eccentric or insane appearance or conduct of the individual will be found to have given rise to an accusation founded on a *bona fide* belief in the individual's actual or potential guilt. Sometimes the insanity will reveal itself in wild and ecstatic utterances of the individual at whose instiga-

tion or upon whose evidence a charge is sustained against a reputable and unoffending neighbour. Sometimes the mixture of hysteria or epilepsy with a malicious or criminal disposition will mask the real character of the case and give, as in any form of criminal charge, grounds for the expression of honest though contradictory opinion on the two sides.<sup>70a</sup>

Proposals to honour the memory of Sir Thomas Browne in 1904 brought an indignant letter to the *British Medical Journal* from the Irish alienist, Conolly Norman, recalling how Browne's "expert testimony" in 1664 secured the conviction and execution of two women tried for witchcraft before Sir Matthew Hale.<sup>72</sup> A lively correspondence followed this letter, which created a brief flare-up of interest in the subject of witchcraft and medical responsibility; but, brief as it was, the discussion tailed off into historical reminiscence before it died down. In the following year, Norman published an interesting study on the reappearance among modern paranoiacs of notions having the closest connexion with old witchcraft delusions. He suggests that the wonder-working delusional inspirations of the insane are taken from the material provided by their own times, e.g. in the 20th century from such developments as electricity and the phonograph.<sup>73</sup>

The New England witchcraft excitement of 1692, brief but intense and bitter, roused some modern medical curiosity by its local character and the completeness of its documentation.<sup>61 62 70</sup> Taylor<sup>70</sup> comments on the remarkable lack of critical interpretation of witchcraft phenomena from a medical standpoint, but in his own interpretation concentrates on "the pathological significance of the disorders observed in the bewitched persons" with no reference to the character of those accused. Caulfield<sup>62</sup>, on the other hand, begins by taking the suspected persons into review: "Goody Osburn, a sickly old creature, who later at her trial admitted that she suffered from vivid dreams"; "old Sarah Good, a pipe-smoking, disorderly, somewhat demented beggar." His paper is paediatric in intention, but he does not miss the significance of the "afflicted children's" selection of these old women for accusation, and brings out well the suggestibility of children brought up in the peculiar atmosphere of Puritan New England.

Tramer's paper,<sup>77</sup> again concerned with child psychology in relation to the witch-beliefs and trials, also draws attention to the type of ragged, hunch-backed, dishevelled, emaciated old woman presented to child-belief as a witch. One or two other authors have referred the suspect behaviour of supposed witches to schizophrenia and epilepsy<sup>64</sup>, to trance-mediumship or essays in extra-normal experience<sup>61</sup>, or to unrealistic symbolism.<sup>64</sup> The remaining few who have concerned themselves with witchcraft and medicine have been mostly interested in the belief in the magical causation of disease.<sup>63</sup> Zilboorg, in his *History of medical psychology*, and other contributions<sup>81 82 115 116</sup> alone gets the phenomena of witchcraft into a true perspective in medical, psychological and social history. But the problem still awaits handling by the geriatrician.

### Psychological and Social Sources of Prejudice Against Old Women

The psychopathology of old age is now beginning to be well documented.<sup>83-105</sup> In 1931 Critchley anticipated the present preoccupation with psychological phenomena of ageing<sup>66</sup> and, as early as 1896, Scott<sup>102</sup> had some good

things to say about reactions to old age viewed as the diminuendo of life. Hall's book on senescence,<sup>92</sup> which appeared in 1923, stands in a class by itself; it was the rounding off, in retirement, of a professional career which had already contributed full and specialized treatments of the phenomena of adolescence and maturity. It is only within the last decade that the mental state of old people, and the happiness or unhappiness of their reciprocal relations with the community, have come to be realized as a factor to be reckoned with in communal welfare.

The published results of research reveal a recognizable pattern of senile psychosis, with recurring traits such as neglected appearance, forgetfulness, confused and agitated behaviour, incomprehension of personal danger, and a variety of antisocial psychopathies ranging from mild suspiciousness to homicide, imagined or actual. These and other related traits become familiar to the point of monotony in any intensive reading of the original witchcraft data.

East, in an important paper on the aged criminal offender,<sup>89</sup> draws from his own medicolegal experience conclusions for which endless evidence could be found in the witchcraft records. He quotes, among other illuminating cases, that of a man of 75 who had murdered his landlady for alleged reasons based on "delusions inherently incongruous." The behaviour of this man at the medical inquiry into his mental condition, *after* the trial at which he had been found guilty and sentenced to death, is strongly reminiscent of that of many of those accused as witches, as described in the 16th and 17th century narratives. East observes:

Confusion of thought . . . unwarrantable distrust of others and suspicions regarding events, restlessness and resistiveness mark the passing of normal senescence into abnormal senility and suggest to the forensic psychiatrist the lines upon which to shape his evidence in a criminal court.

The question of responsibility and culpability, in actual or imagined crimes, was not unthought of by the contemporaries of the supposed witches. Selden<sup>93</sup> would have had them punished even by death for malicious intent, declaring:

If one should profess that by turning his hat thrice and crying buz, he could take away a man's life, though in truth he could do no such thing, yet there is a just law made by the State, that whosoever should turn his hat thrice and cry buz, with an intention to take away a man's life, shall be put to death.

Diefenbach quotes a whole series of doctors of the time who professed very similar views.<sup>47</sup> Zilboorg<sup>117</sup> reminds us that what we now know as "neurosis" and "personality deviations" presented no problems to the physicians of those days, not because these deviations did not exist, but because they were all "commonly understood to stem from ill will, which covered the whole length of the series from mere naughtiness and prankishness to psychopathies and criminality. The concept of ill will was the most dynamic and potent one in the history of witch-hunting." Weyer took the view we should expect of him: "If one holds that witches are to be severely punished for their evil intent, let it be remembered that there is a great difference between sane and insane will".<sup>95</sup> But it is the layman, Scot, who takes us to the heart of the matter, giving us a sharp reminder of helpless old women caught up in an unhelpful world. "Their wrongs," he cries, give them leave "to chide and threaten, as being void of any other waie of revenge."<sup>92</sup>

Insanity alone is a too easy explanation. Ackerknecht<sup>90</sup> gives us a timely reminder that "being different is not yet being psychopathological" and points out that the psychopathology of the odd ones of society, such as homosexuals, mulattos or hunchbacks, is due "much more to their ambiguous position than to their organic structure." For more than two centuries, old women were unquestionably among the odd ones of society and had a distinctly equivocal position. The centuries of the witch persecutions were a time of social stress, of changing economy, of storm and clash of creed. The issues became as confused in the minds of the constituted authorities as of the people; the passionate fight against heresy and apostasy became identified with the ancient hatred of witchcraft.<sup>81</sup> For the underlings of society—the poor, the infirm and the old—there was little joy in Elizabeth's Golden Age, the age of discovery and invention, of the rebirth of science and the revival of letters. As long as a Glanvill could fight with equal vigour and enthusiasm both for the Royal Society and for witch-belief, it was not the defence of science that affected these vulnerable ones.

Reviewing the factors contributing nowadays to mental disease in old age, Stieglitz<sup>104</sup> says, "migration from rural to urban areas, with the greater complexity of life, puts many old people in the category of being incompetent to continue free in society." Geriatricians today have found in cases of senile psychosis that the precipitating agency into psychosis is most frequently some form of loss of social integration, as loss of home or spouse or other relative, or a feeling of insecurity, defeat, or humiliation.<sup>87 88 99 105</sup>

Numbers of poverty-stricken old women who had outlived family and friends, or been left behind by them in the migration in quest of easier living, must have been caught up into that time of intensified religious emotion and fear, economic distress and general bewilderment. The prevalent beliefs in witchcraft provided ready-made moulds for the fancies of any sick or unhappy mind seeking satisfaction in the delusional transformation of reality. Their very appearance, behaviour and tormented bad temper would make these old women ready scapegoats for a sick and oppressed society.

Defoe, the man of many indignations, writing in 1727, found in the witch-persecutions evidence for his "complaint against the brutality of the present age: particularly the pertness and insolence of our youth to aged persons . . ." He says: "Those were brave days for young people, when they could swear the old ones out of their lives and get a woman hanged or burnt for being a little too old . . . and as a warning to old ancient persons, who should dare to live longer than the young ones thought convenient."<sup>108</sup>

In 1767, Stephen Fovargue catalogues witch-belief as a vulgar error, along with beliefs that negroes are not a part of the human species, and that the hedgehog is a mischievous animal.

It may be objected here that former legislators have thought proper to allow a reward to be given for killing this animal . . . to which I answer that legislators have thought proper to burn old Women, for being Witches . . . and I will venture to affirm that there is just as much sense in burning a Witch as in setting a Reward upon a Hedge-Hog.<sup>110</sup>

An early socialist hymn of 1849, on "The Days that are Gone", sings of

When famine and age made a woman a witch  
To be roasted alive or be drowned in a ditch.

Thus later popular and literary memory provided its own diagnosis.

Yet another aspect is provided by some of the contemporary evidence. White, in his *History of the warfare of science with theology*,<sup>58</sup> quotes physicians of the time of Weyer as deprecating interference with the existing belief in witchcraft because it seemed to them a "very safe belief to be held by the common people." Something of this attitude seems to have been present in the episode described in a letter from a friend to Cornelius Agrippa, the teacher of Weyer. He writes of "a certain decrepit old woman," who

being exposed . . . to dire tortures, confessed herself, under excruciating pain, to be a witch, to have denied Christ, on the suggestion of an incubus, to have flown through the air, to have raised storms, to have inflicted damage and disease on man and cattle.

After she had been convicted and duly burnt, Savin, the master of the heretics, publicized and emphasized the details of the confession and incited the populace to a witch-hunt. To us moderns, unhappily aware of lynching and pogroms in our own times, there is something horribly familiar in the lines that follow: ". . . There is a murmuring of the mob against poor little women, a detestable hatred springs up. Here and there the peasantry confer together and many crippled old women are seized, but most run from the danger."<sup>59</sup>

#### The Problem for Mental Science

The history of witchcraft of the 16th and 17th centuries is apt to be obscured by clouds of theory and dogma concerning cult and occultism. Davies's book<sup>46</sup> is perhaps unique in its treatment of the witch-beliefs as a functioning part of the mosaic of major events and minor happenings that make the pattern of contemporary history. Probably the truest picture is that given in the pamphlet literature; allowing for the newsmonger's sensationalism, it is easy to extract the residuum of fact—the position of the accused witch in her community, the real ground of the feeling against her on the part of her neighbours, the way in which the alarm spread, the processes used to elicit confession.

The investigator is beset with warnings. "Each country has its own type of witchcraft."<sup>59</sup> While England had its Matthew Hopkins and Scotland its "common witch-prickers" exploiting popular fear to the tune of twenty shillings search-fee per village plus twenty shillings per head for every witch brought to judgement, even the more scholarly and ritual attitude towards witches in Germany could tolerate its *Hexenspiörer*, its Lutherus Einhorn to pursue Kepler's mother with all the bitterness of his slogan, "To the stake with all old women."<sup>59</sup> Another warning is in the oft-repeated argument that it was not only aged

women who were prosecuted for witchcraft or were professed practitioners of sorcery. This is equivalent to arguing that, because patients of all ages are subject to chronic illness, the urgent need for beds for the chronic sick is not specifically a problem of geriatrics. The weight of evidence in both cases is on the side of the overwhelming numerical preponderance of the old.

A serious and more valid warning is against the danger of projecting the values of our times into the experiences of those days. Ackerknecht<sup>60</sup> reminds us that what is regarded as psychopathological behaviour now may have been normal in other times and conditions, and Maudsley<sup>61</sup> recalls that the same caution applies to the diagnosis of insanity from behaviour, in the circumstances of different, though contemporary, strata of society.

When all these doubts and differences have been cleared away, there remain certain phenomena bearing such strong resemblance to phenomena of our own times that we may be justified in believing that their study will reveal some permanent laws of cause and effect. There is today a growing tendency for doctors to be reminded that "patients have families"<sup>114</sup> and to pay more and more attention to the social history of the patient. There is also an increasing trend towards the study of the nature of persecutions, analyzing the psychology and reciprocal relations of hunter and hunted, the oppressor and the oppressed, the holder and object of prejudice.<sup>107 109 111 113 115 116</sup>

The old women who were accused of witchcraft had families and neighbours with whom they passed their daily lives, sharing their poverty or depending on their prosperity. They lived in times when, on the one hand, the now known features of senile psychosis could be sometimes driven over the borderline from mild confusion to raving insanity, sometimes aggravated into a desperate hostility towards society; and when, on the other hand, all the prejudice of society was concentrated against old women—even the most helpless and harmless—to such an extent that children were impregnated with it from their nursing days. "For," cried Reginald Scot,

. . . the world is now at that stay . . . that even as when the heathen persecuted the christians, if anie were accused to beleve in Christ, the common people cried *Ad leonem*: so now, if anie woman, be she never so honest, be accused of witchcraft, they crie *Ad ignem*.<sup>21</sup>

The striking problem which emerges for mental science is that of a twofold antisocial psychopathy—of society against old women and of old women against society. Our easy assumptions about what is "natural" in human reciprocal relations need to be re-examined in the light of how these assumptions change or endure with change of time or circumstance. By such examination, much light may be shed on some of the darker problems of our own day.

## HYPNOTISM AND SUGGESTION: THEIR PLACE IN PSYCHOTHERAPY

WILLIAM BROWN M.A. M.D. D.Sc. F.R.C.P.

*Formerly Director, Institute of Experimental Psychology  
University of Oxford*

Hypnotism and suggestion have been studied for many years by observational methods, but it is only quite recently that experimental techniques have been brought to bear upon them. The first piece of research work done at the Institute of Experimental Psychology at Oxford after its foundation in 1935 was on this subject: much work has also been done in the USA. Let me come at once to the central problem: What is the nature of the hypnotic trance? Are there definite,

objective, physical criteria associated with this condition? The extent to which the term "hypnosis" can be applied still awaits determination, but the mental state which undoubtedly deserves this term is the hypnotic trance. This may be defined as a secondary state of mind, produced by definite methods—not one single method—leaving behind it amnesia or loss of memory for that particular mental state, and at the same time, or alternatively, involving pronounced anaesthesia to painful sensations. It is, in other words, a condition of artificial somnambulism.

This state of artificial somnambulism was first recognized by the Marquis de Puységur in 1784. In the course of his researches, he was fortunate in meeting a shepherd boy named Victor, a subject who readily passed into a state of *lucidité* in which he seemed to be aware of things not otherwise known, some of these things proving to be accurate when tested. This started a furore which is described by Pierre Janet (1919) in his great book, *Les médications psychologiques*. As the whole subject was frowned upon by the medical profession, medical men who took part in this work had to disguise their activities. Is this state of *lucidité* genuine? There is no question that there are plenty of fakes, and that often it is not genuine. Such cases must be investigated very strictly indeed; the imagination is so vivid, and subconscious influences so profound, that deception, and even self-deception, is possible and perhaps frequent.

*Laboratory Studies: the Electroencephalograph*

In the latest experimental work the electroencephalograph has been employed, and work with this instrument is described in an article by J. B. Dynes (1947) of the Lahey Clinic, Boston, Massachusetts. In 1936 A. L. Loomis published an article in the USA in which he studied one single case, comparing the state of hypnosis with the state of sleep. Loomis found that the electroencephalogram of the subject in hypnosis was indistinguishable from that of the same person awake, but quite different from that obtained in normal sleep. Loomis, unfortunately, did not publish his electroencephalograms; Dynes, however, verified these results, experimenting with five good hypnotic subjects. His published diagrams make it perfectly clear that these subjects, in a state of somnambulism with subsequent amnesia, and with insensitivity to ordinary painful stimuli, gave the same kind of electroencephalogram in the hypnotic state as they did when awake.

In 1931 M. J. Bass, working in the USA, studied the changes in the knee-jerk in the subject under hypnosis, and recorded the response in kymographic tracings. He discovered that as the subject falls more and more deeply asleep the knee-jerks diminish until they practically disappear. In the hypnotic state, on the other hand, although outwardly he may seem to be asleep, his knee-jerks remain. Dr. W. Stephenson and I repeated this work at Oxford in 1936, and verified that the state of hypnosis is an active one, in which the tendon reflexes persist. I give the record of the knee jerks of one undergraduate subject, 22 years of age, from my book, *Psychological methods of healing* (Brown, 1938).

**FIG. 1. KNEE-JERK MEASUREMENTS DURING HYPNOSIS**

(Reprinted from Brown, *Psychological methods of healing*, fig. 1, p. 117.)

Each vertical line is the average of 4 consecutive measurements of the knee-jerk stimulated at 10 sec. intervals.

N : normal knee-jerk, subject wide awake

A : suggestion, "Go to sleep", given; and repeated at intervals between A and Z

Z : development of hypnoidal state

H<sub>1</sub> : right arm catalepsy on strong suggestion that subject cannot drop the arm. Note reinforced condition of knee-jerk

H<sub>2</sub> : return to relaxation with suggestion

B to C : gradual return to waking state and to normal knee-jerk

Gradually, as I suggested sleep to him, the knee-jerk became less and less, down almost to nothing; as soon as I began to give any other kind of suggestion, to which he responded although he remained perfectly passive and quiet, back came the knee-jerk. Only when the hypnosis passed into a state of sleep again did the knee-jerk disappear once more (fig. 1). In a sense, therefore, hypnosis is active and sleep is passive; every objective test which we can devise points in the same direction.

*Clinical Application of Hypnosis*

In my own work, in the First World War, I was concerned with thousands of cases in the British Fourth Army in France from 1916 to 1918. Some 600 cases showed pronounced amnesia in addition to other functional nervous symptoms, and most of these cases were very easy to hypnotize. In 125 cases of amnesia with functional aphonia the ability to speak was restored when their lost memories were recalled under hypnosis. I found that one had to be firm and emphatic with them, in order to overcome the resistance they subconsciously put up to the recall of their terrifying front-line experiences.

What are the objections to hypnosis? Hypnotic trance can be produced in about 20 or 30 % of apparently normal people, but it is most easily produced in people with functional dissociation, especially functional amnesia. When such a person is hypnotized and the memory restored, and with the memory sometimes other lost powers such as walking and talking, the patient is left hypnotizable and likely to become more and more so with repeated treatments. He also becomes more and more dependent on the hypnotist. Psychological methods of re-association and unification of the patient's mind have to be employed to neutralize these bad effects. This means the systematic use of analytical psychotherapy to complete the treatment.

*The Use of Suggestion*

For these reasons I use hypnosis as little as possible in my practice. I use instead the suggestion of relaxation; this checks the onset of any deep hypnotic state or trance in most cases. If the subject is easily hypnotizable, he can of course be put into a hypnotic slumber from which he wakes up unable to remember what has happened. But if, before waking him up, the suggestion is given that he will remember everything on waking, the suggestion always works and he becomes re-associated and, in consequence, less hypnotizable than he had been previously.

The relaxation of the muscles by suggestion does not make the subject more hypnotizable, but rather the reverse. There is a difference between hypnosis and suggestion, although they are most intimately related. The great discussion in France toward the end of the last century was between Charcot, who described hypnosis as a mental dissociation or "artificial hysteria", and Bernheim, who repeated Charcot's experiments and defined hypnosis as "an artificially increased suggestibility". Bernheim was wholly right, but Charcot was not entirely wrong. Charcot dealt with very easily hypnotizable subjects, whereas Bernheim had a predominantly therapeutic purpose. In dealing with cases of functional disorder, one always wishes to strengthen their will, but with deep hypnosis one is sometimes working in the opposite direction. Hypnotism is indeed a mental drug: it paralyzes the will, unless supplemented by more active psychotherapy.

Suggestion, on the other hand, is a successful appeal to the unconscious. Therapeutic suggestion is not bluff; the suggestions made are, or should be, in harmony with reason. The doctor says to the patient: "You can get well by a change of mental attitude and outlook, because you are suffering from a functional nervous trouble." Progressive relaxation can be secured (by deep breathing and

*Continued at foot of page 74*

## SHOULD ANTHROPOID APES BE EXCLUDED FROM THE HUMAN FAMILY TREE?

Sir ARTHUR KEITH M.D. F.R.C.S. LL.D. F.R.S.

*Master, Buckston Browne Research Farm, Kent  
Former President, Royal Anthropological Institute*

I am sure that if anthropoid apes, such as the gorilla and chimpanzee, were acquainted with recent anthropological and anatomical literature, they would be incensed about the strictures passed on them by Professor Wood Jones. Away back in the sixties and seventies of the last century Darwin and Huxley hailed them as man's nearest surviving relatives; ever since, they have been given that high place by practically everyone who has dealt at first hand with the problem of human evolution—all save the author of the book<sup>1</sup> now before us. It is now thirty years since Professor Wood Jones turned his back on the anthropoid apes and excluded them ignominiously from any place in the evolutionary tree of mankind. In his most recent work, *Hallmarks of mankind*, there is no sign of softening; on the contrary, his attitude is now almost vindictive. Being gifted with those mental qualities which give men eminence at the Bar—clarity of thought, an easy flow of ideas and phrases, a style of writing which is at once attractive and emphatic—the case he has now stated would carry an uninformed jury with him. What I have against his statement of the case is that it is entirely one-sided; the “pros” are emphasized, the “cons” are omitted. The anthropoids are in need of a defender.

One can see the first signs of a changed outlook on evolutionary problems in the excellent book Wood Jones published in 1916 with the title *Arboreal man*. In that work we meet with traces of uneasiness about how man

<sup>1</sup> [For particulars, see Book Reviews, p. 122.]

had come by his ‘primitive’ structural characters. In 1918 came what may be called his confession of evolutionary faith; it was but a booklet, with the title *The problem of man's ancestry*, but it contained all the arguments and evidence now restated in the *Hallmarks*. To account for the presence of man's primitive features and the absence of simian or apish characters, Professor Wood Jones believed it to be necessary to go back to the infancy of mammalian life and bring man off from the primate stem, before that stem had given origin to Old World monkeys and anthropoid apes. He agreed then, and indeed still does, that man and anthropoid apes have a great number of structural resemblances but holds that man and ape came by these resemblances independently. The pro-anthropoid evolutionists, on the other hand, hold that man and anthropoids have so many characteristics in common just because they have arisen from the same primate stem.

The argument of 1918, formulated as the First World War came to an end, concluded with an ethical note which does not appear in *Hallmarks*, but which I believe has influenced the author now in drawing up his scheme of human evolution. This ethical apologia covers the four last pages in the booklet of 1918, but its general trend will be sufficiently apparent if I quote merely the final sentence:

Were man to regard himself as being an extremely ancient type, distinguished now, and differentiated in the past, purely by the qualities of his mind, and were he to regard existing Primates as misguided and degenerated failures of his ancient stock, I think it would be something gained for the ethical outlook of humanity—and it would be a belief consistent with present knowledge.

The friendship between Professor Wood Jones and myself covers more than half a century; I know his tenderness of heart, his hatred of all forms of cruelty and aggression, his sympathy for the underdog and his partiality for neglected causes; yet these qualities, so beneficent in ordinary life, may be dangerous if permitted to influence scientific judgement.

There was something almost parricidal in the publication of that booklet of 1918 by Wood Jones. For he and I had come together at the London Hospital in the closing years of last century, he as a student of medicine and I as a teacher of anatomy. He was the ablest pupil I ever had. When we first met I was bringing to an end a ten years' period of intensive research into the anatomy of apes and man; I had sacrificed everything for that research. I had collected a much greater array of evidence bearing on the structural relation of man and ape than was at the disposal of either Darwin or Huxley. As is the manner of young

## HYPNOTISM AND SUGGESTION

*Continued from page 73*

suggestion), starting with the voluntary muscles and then spreading to the involuntary muscles controlling the blood vessels, lungs, and gastro-intestinal tract. In my opinion this spread of relaxation takes place in what I call the “post-respiratory pause” and I have found that relaxation can be augmented by voluntary

retardation, for one or two seconds, of the next inspiration. This relaxation will beneficially affect the autonomic nervous system with its central connexions. In the state of relaxation there is response to self-suggestion, the stepping-stone to the will; and along these lines lies the hope of successful therapy.

ambitious men, I had hoped to find a hole in their armour, but when I had systematized all my evidence I found that it but supported their main contention that man's nearest surviving relatives are the anthropoid apes. Readers will now understand why the bomb thrown by my old pupil in 1918 hit me particularly hard. It was not the dethronement of the anthropoids which hurt me; it was the magisterial way he relegated my ten years of labour to the lumber heap.

Ever since 1918 the tide of evidence has favoured more and more those who regard the anthropoids as man's nearest surviving relatives. Man's chief distinguishing feature—his essential "hallmark"—is his brain. The neurological surgeon, when in need of fresh light on the human brain, finds what he is in search of in the living brains of anthropoid apes; the psychologist in search of the beginnings of human mentality finds them in the mental manifestations of the anthropoids. In the matter of blood groups and in their reactions to disease the great anthropoids make the nearest approaches to man. The hallmark of a close and true relationship between the anthropoids and mankind is found in their identity of placentation; the complex and peculiar method by which the fertilized ovum establishes itself in the womb is identical in both. The nearest thing in all the living world to a new-born babe is an infant anthropoid. All of these resemblances are recognized by Professor Wood Jones, but he holds that man and anthropoid have come by them independently. Nor has he been influenced one whit by the labours and discoveries of geneticists and modern students of heredity; he explains evolutionary change in the same manner as did Lamarck.

#### The Record of the Rocks

All disputes as to the exact evolutionary relationship of man and anthropoid will be finally settled by "the record of the rocks". The fossil anthropoids of South Africa show a medley of anthropoid and human characters; if nothing but their teeth and jaws had been found, these anthropoids would have been given a place in the human line of descent. In face, skull and brain they are anthropoid; their pelvises show both anthropoid and human features. The discovery

of such an intermediate type I regard as conclusive evidence that man and anthropoid belong to the same evolutionary stem. That is not how Professor Wood Jones interprets the mixture; for him the South African fossil forms "... are merely apes that fall short, in some respects, of attaining all the specialisations of their modern representatives." (p. 86)

Most of us see in the fossil anthropoids of South Africa an anthropoid assuming 'humanoid' characters; Wood Jones, on the other hand, sees a humanoid form evolving in an anthropoidal direction. In any case the close relation of man and anthropoid is realized by both of us. In the human face all outward trace of the premaxilla has disappeared; its disappearance, in our author's opinion, is the chief of man's "hallmarks". In the South African anthropoids, as in all primates, the premaxilla maintains its separation from the maxilla, and on this account is excluded by Professor Wood Jones from the human line of descent. He seems to deny the possibility of the snouted face of the anthropoid evolving into the retracted form of the human face.

Lately Dr. L. S. B. Leakey discovered in the lower Miocene deposits of East Africa the skull of an anthropoid ape—the earliest and most complete specimen that has yet come to light. The face is complete and there is attached a large part of the skull. The ape thus discovered was smaller than the chimpanzee. Its most striking characteristic is the degree to which it has retained, in its adult stage, the cranial features of infancy; all the brutal simian features are undeveloped. It is an anthropoid skull but, being devoid of what Professor Wood Jones calls "simian specialisations", has human resemblances. For me, it is an anthropoid ape making approaches in a human direction, but I am sure such would not be Professor Wood Jones' interpretation. For him it will be a scion of the human stem passing in a simian direction. And here I must leave the problem. Whether the reader believes that the general trend of evolution has been to convert the "lower" into the "higher" forms, or whether he believes in the inverted scheme of Professor Wood Jones, in which the "higher" form appears first and the "lower" is evolved from it, he cannot fail to recognize how closely interrelated are the evolutionary histories of Man and Ape.

## HOW MUCH DO CHILDREN EAT?

J. R. MARRACK D.S.O. M.C. M.D.

*Professor of Chemical Pathology  
University of London*

In most of the nutrition surveys that have hitherto been made the diets consumed by families have been measured; the results have given little information about the distribution of food between different members of those families. The total number of children whose diets had been measured before Dr. Widdowson made this survey was not more than a few hundreds, and these studies were made in various countries over a period of some 50 years, during which knowledge of nutrition grew and the attitude to children and their food changed profoundly.

For the present survey, *A study of individual children's diets*,<sup>1</sup> the diets of 435 boys and 481 girls aged 1 to 18 years, as well as those of 112 children in special groups, such as diabetics, were measured. The total number was therefore 1,028, and there were at least 20 boys and 20 girls in each age-group. More than half the children lived in London and only 36 in Ireland, Scotland, Wales and the Channel Islands. The parents of 36% of the children were of the professional class (doctors, lawyers, solicitors, company directors, and university, public-<sup>2</sup> and secondary-school teachers); 52% of the upper working class (accountants, bank clerks, shopkeepers and the like); 12% of the artisan class (fitters, skilled labourers, lorry drivers, factory hands, etc.). Only a small proportion of the children, therefore, belonged to really poor families. Most of the data were collected in the years 1936-38, with a small fraction in the second half of 1935 and the first half of 1939.

The children, or their parents, were supplied with a spring balance, reading to  $\frac{1}{4}$  oz., a sheet of instructions and a set of forms on which to enter results. Proximate principles were calculated from the tables of McCance & Widdowson (1940); vitamins A, B<sub>1</sub> and D from the tables of Fixsen & Roscoe (1938, 1940), Fixsen (1938) and the Medical Research Council (1945). Olliver's (1943) figures were used for calculation of vitamin C, allowance being made for losses in cooking.

Boys and girls of the same age ate about the same amount up to the age of 13 or 14; after this age boys ate more of most foodstuffs, while girls tended to eat rather less, particularly of potatoes. Above the age of 13, boys ate considerably more sweets and chocolates than girls, which is unexpected. Of bread, only one boy ate over 16 oz.<sup>3</sup> per day and only 1 girl over 12 oz. The amounts of certain foods eaten by some of the children are surprising. In one

week a 15-year-old boy and a 14-year-old girl ate, respectively, 28 and 31 oz. of butter; a 17-year-old boy ate 96 oz. of meat (raw weight) and in every age-group of boys over 12 the maximum amount of meat eaten was over 70 oz.; a 14-year-old boy ate 44½ oz. of tinned fruit; one boy of 15 ate 21 oz. of sweets and 32 oz. of chocolate during one week of the holidays. On the other hand none of the children took as much as 2 pints<sup>4</sup> of milk per day and only one boy ate over 12 oz. of potatoes per day. The average boy, in all age-groups but one, got more Calories from sugar than from bread. It is not surprising that 2 or 4 years later some of these children found adaptation to rationing difficult.

The data of the diets were collected for a week; the question arises, how far can the consumption in one particular week be considered representative of the consumption of an individual? Widdowson measured the number of Calories taken by 36 children on each day of a week and thought that there was a "huge" variation; but the maximum day's intake was rarely over 1½ times the minimum of the same child, which is less than might be expected. In 8 cases the diets were measured for 4 consecutive weeks. The variation was much less; the biggest difference between the weeks of highest Calorie intake and lowest Calorie intake was 33%; in 4 cases it was less than 13%. The diets of 8 boys were measured during a week when they were at boarding school and during a week at home; they ate the same number of Calories in the two weeks.

Not even the day-to-day differences would account for the differences between the intakes of individuals of the same age, which certainly are huge. In almost all the age-groups the maximum number of Calories taken by an individual was twice the minimum, and in two age-groups it was 3 times. The variations between the intakes of children of the same height, weight and surface area were about as great as between the intakes of children of the same age. It seems that these great differences can be accounted for only by great differences in the efficiency of individuals as machines.

The number of Calories taken per day in all the age-groups ran very close to estimated requirements, such as those of Cathcart & Murray (1931) and of the National Research Council, USA (1943); but the consumption by boys aged 15 to 18 and by girls aged 10 to 15 was rather less, and consumption by girls of 16 to 18 rather more, than the N.R.C. estimates. Total protein runs so closely parallel to Calories that the intake also must agree fairly well with estimates. The average animal protein was about two-thirds of the total protein, as recommended by Holt & Fales (1921).

No allowance was made for the calcium in tap water, which might amount to about 0.1 g. per day when the water was hard. Boys and girls up to 10 years of age got about 0.8 g. per day; girls over 10 years got 0.6 to 0.7 g. The intake of aneurin fell from about 0.5 mg. per 1,000 Calories at the age of one year to 0.35 mg. at 10 years. The average total ascorbic acid ranged from 41.5 to 79.8 mg. A large proportion was derived from citrus fruits, particularly by girls but not by boys over 15. Carotene, reckoned to have  $\frac{1}{2}$  its nominal vitamin A value, provided under 1,000 i.u. per day and, in most age-groups, considerably less than

<sup>1</sup> [For particulars, see Book Reviews, p. 122.]

<sup>2</sup> [See footnote<sup>2</sup>, p. 52.—Ed.]

<sup>3</sup> [1 ounce = 28 g.—Ed.]

<sup>4</sup> [1 pint = 0.568 l.—Ed.]

was provided by liver. The average preformed vitamin A, derived from foods other than liver, was over 1,000 i.u. in all age-groups, but the only age-groups that averaged over 2,000 i.u. were boys of 15 to 18 years. Most of the children who did not eat liver got between 1,000 and 2,500 i.u. per day. Fat fish supplied a large proportion of the vitamin D; whereas the average intake by children who ate fat fish was over 100 i.u. per day in all age-groups, the average intake by children who did not eat fat fish was less than 90 i.u. per day.

The relation of the consumption of various foods to locality and class was studied. The children of the upper working class got most milk and those of the artisan class least. Only 19% of boys of the professional class took milk at school. Children in S. and S.W. England got most milk and children in N. England least. No consistent differences in consumption of fruit and green vegetables were found. The food was most varied in children of the professional class.

Variations in intake of Calories must be limited by hunger and satiety. Intakes of minerals and vitamins by different individuals naturally vary much more; thus one boy aged 14 years took 30 times as much ascorbic acid as another of the same age. Is there any evidence that these great variations have any relation to the rate of growth or health of the children? The heights and weights of all the children were measured; haemoglobin estimations were made on 189 boys and 200 girls; the teeth of 183 boys and 207 girls were examined with a probe and mirror. As already mentioned, the heights and weights of children seemed to have no relation to their intakes of Calories; they were no more

closely related to intakes of animal protein. The concentration of haemoglobin was not related to the intake of iron. Most of the children had bad teeth; the incidence of dental caries was not related to the amount of calcium in the food. Twin brothers, aged 7, took almost identical amounts of calcium (0.87 g. per day); one had 12 carious teeth and another had none. In the extreme case, children of unemployed parents, whose diet was consistently limited by poverty and not by appetite, were smaller than the average. Children who drank much milk were no better grown than children who drank little. But children who are small for their age are encouraged to drink milk, so that it might be expected that a small child would drink more than the average.

We cannot learn from studies of this kind what happened before and after the week of investigation. It often happens that a child with a poor appetite suddenly becomes a big eater; that a child who disliked some food begins to eat it. The investigations show what the child was eating at the time, but its physical state is the result of what it got in the past. We need some surveys in which individuals are studied over periods of years to see what happens in the end to these big and small eaters.

This investigation has given a wealth of information about the food habits of children. It will be of the greatest value, in years to come, to those who want to know how people lived in the 1930's. Dr. Widdowson has worried out all the information that could be got from the data. It would be interesting to know how much she used mechanical methods of analysis; whether in fact all this information could be extracted by mechanical methods.

## EUGENICS: INTELLIGENCE AND GENIUS

SIR CYRIL BURT D.Litt. D.Sc. LL.D.

*Professor of Psychology  
University College, London*

These two pamphlets<sup>1</sup> are the third and fourth of the Occasional Papers on Eugenics, issued by the Eugenics Society. They continue the themes taken up by the first two contributors, namely, Dr. Blacker, who reviewed the whole subject of *Eugenics in prospect and retrospect* (1945), and Sir Cyril Burt, who discussed the relations between *Intelligence and fertility* (1946)<sup>2</sup>.

The earliest evidence, showing that there is, in this country at any rate, a negative correlation between the intelligence of children and the size of the families to which they belong, would seem to have been that reported in the surveys of the Psychologist to the London County Council between 1915 and 1921. Both Galton and Karl Pearson had drawn attention to a negative correlation between fertility and social status. But the psychological inquiries carried out among the London school population furnished direct evidence for a negative correlation between fertility and intelligence, and showed that it obtained even within members of the same social class.

Professor Thomson tells us that his interest in the problem dates from about the time when these results were published. He himself then independently noticed a similar correlation while testing school children in Northumberland; and he describes in detail several direct attacks which he has since made on the problem, in conjunction with various collaborators. He ends his discussion with a section on the factors of the mind. Thirty years ago, when factor-analysis first came to the fore, Professor Thomson was one of the severest critics of the existence of a so-called 'general factor', which psychologists of those days identified with what Binet called 'intelligence' and Galton 'natural ability'. It is therefore highly encouraging to find that he now accepts the view that, on the intellectual side, the mind may be assumed to consist both of a general factor and a number of special abilities operating as group factors, and that of these intelligence, defined as an innate, general, cognitive capacity, is by far the most important. He discusses the view that, although intelligence in one form may be declining, there may nevertheless be a possible compensation owing to the "increase in some other form of intelligence"; and eventually rejects it. "I think", he concludes, "that intelligence is much more one thing than such a view would

suggest"; and he believes that the higher level of intelligence "is being steadily lost to Europeans by the selecting power of the differential birthrate."

The pamphlet contains supplementary contributions by Sir Alexander Carr-Saunders, Sir Cyril Burt, and Professor Lionel Penrose. In the main all the contributors appear agreed upon the essential facts, and upon the need for a more direct psychological attack upon the problem.

Professor Terman's pamphlet is a summary of a "twenty-five years' follow-up of a superior group". The full details have been published in a volume recently issued by the Stanford University Press under the title, *The gifted child grows up* (1947). Professor Terman and his colleagues began by carrying out surveys in certain urban areas of California with a view to discovering the children who possessed the highest intelligence quotients. Just over 1,500 boys and girls were identified with quotients ranging from 135 to 200 or a little over. Using Taussig's socio-economic scale, he found that 31% came from class I (professional classes), 50% from class II (semi-professional and business), 12% from class III (skilled workers) and only 7% from classes IV and V (semi-skilled and unskilled labour). From time to time reviews have been made of the same group as it has grown up; and, at the time of the most recent survey (1945), it was possible to secure data for 97% of the original number.

Professor Terman reminds us that, when his investigations were first planned, the current belief, held by most medical men, depicted the so-called precocious child as an abnormal or neurotic creature, "headed, if he survived at all, for post-adolescent stupidity or insanity". The educational corollary was that "the bright child should be protected from intellectual stimulation and any tendency towards early cleverness should be positively discouraged". Even now one still encounters general practitioners and even school medical officers acting on this maxim in the advice they give to parents. Terman emphasizes that the after-histories of his group completely disprove these pessimistic forecasts. As regards physique, health, and mortality, the intelligent child is definitely superior to the average population. The number among whom mental maladjustment has been reported is only 4%; only a fraction over 1% have manifested psychotic disorders. An interesting point brought out by the after-histories is that, even when gifted individuals have succumbed to mental disorder, they generally later show a marked improvement, or even make a complete recovery.

The children of those who are now old enough to have families of their own have also been tested. Their average intelligence quotient is 128—"a regression of somewhat less than half the distance of their parents from the general mean". This, he adds, is in close agreement with Galton's law of filial regression. As regards fertility, he considers it too early for a definite conclusion; but thinks it "very doubtful whether their ultimate fertility will be sufficient to maintain the stock".

The whole inquiry leaves no shadow of a doubt that, by means of suitable tests and other devices, a competent psychologist can nowadays pick out during early childhood those who will prove to be of high intelligence in adult life. This perhaps is most strikingly demonstrated by the adult achievements of the members of Terman's own group. Nearly half the men, and more than half the employed

# Annotations & News

1311

DR. N. HOWARD-JONES O.B.E.

Last year, Dr. Howard-Jones, who was the founder and first editor of the *British Medical Bulletin*, left the British Council to take up the important post of Director of the Division of Editorial and Information Services of the World Health Organization at Geneva.

Dr. Howard-Jones founded the *Bulletin* in March 1943, and continued as editor for five years. Under his guidance, and in spite of war-time difficulties, the *Bulletin*, from a small journal of a dozen pages consisting mainly of abstracts, rapidly increased in size and importance. By his personality, enthusiasm and editorial skill he enlisted the aid of many eminent contributors and won for the *Bulletin* the high reputation it now holds as a medical review, and which it will be our endeavour to maintain.

Our best wishes, and, we are sure, those of our readers, go with him in his new and wider field of activity.

1312

## BULLETIN MEDICAL BRITANNIQUE

In February of this year appeared the last number (vol. 2, no. 4) of the French edition of this *Bulletin*. We much regret the loss of direct contact with readers of the French language which the discontinuation of this edition entails; but the decision was dictated by financial and other considerations beyond editorial control and we can only hope that our French readers will continue to read the *Bulletin*, in its original English edition.

It would be ungracious in this connexion not to acknowledge our debt to Dr. Pierre Lépine of the Institut Pasteur, Paris, for the time and care he gave to the medical editing of the translation of the *Bulletin Médical Britannique* and we gratefully thank him and his team of translators for their valuable help.

1313

## THE ROYAL SOCIETY

The Royal Society recently announced the names of 25 distinguished scientists elected in 1949 to the Fellowship of the Society. Of those engaged in medical research and allied fields we note with pleasure the following, a number of whom have been contributors to the *British Medical Bulletin*:

FREDERICK CHARLES BAWDEN. Head of the Plant Pathology Department at Rothamsted Experimental Station, Harpenden. Distinguished for his work on plant viruses and virus diseases, he has also made important contributions to the study of virus serology.

FRANCIS WILLIAM ROGERS BRAMBELL. Lloyd Roberts Professor of Zoology, University College of North Wales, Bangor. Distinguished for his experimental studies of processes of reproduction in mammals and of the factors concerned in antenatal mortality.

ERNST BORIS CHAIN. University Demonstrator in Chemical Pathology, Oxford University. Distinguished for his work on enzymes of snake-venom and bacteria, and especially for his researches on penicillin and other antibiotics.

HEDLEY RALPH MARSTON. Chief of Division of Biochemistry and General Nutrition, Commonwealth Council for Scientific and Industrial Research (University of Adelaide, South Australia). Distinguished for his researches on nutrition and wool growth in merino sheep and on trace element deficiency diseases in ruminants.

KENNETH MATHER. Professor of Genetics, University of Birmingham. Distinguished for his contributions to genetics and particularly for his studies of polygenic inheritance.

PETER BRIAN MEDAWAR. Mason Professor of Zoology and Comparative Anatomy, University of Birmingham. Distinguished for his studies of growth processes and of the phenomena associated with tissue transplantation.

WALTER THOMAS JAMES MORGAN. Lister Institute of Preventive Medicine; Reader in Biochemistry in the University of London. Distinguished for his contributions to the chemistry of immunology and blood groups.

NORMAN WINGATE PIRIE. Head of the Biochemical Department, Rothamsted Experimental Station, Harpenden. Distinguished for his research on the chemical and physical properties of plant viruses.

DAVID AYLMER SCOTT. Connaught Laboratories, University of Toronto. Distinguished for his contributions to the chemistry of insulin, heparin, and carbonic anhydrase.

WILSON SMITH. Professor of Bacteriology, University College Hospital Medical School, London. Distinguished for his researches on the virus of influenza and on the pathology of staphylococcal infections.

FRANK GEORGE YOUNG. Professor of Biochemistry, University College, London. Distinguished for his studies of the role of the hormones of the anterior lobe of the pituitary gland in carbohydrate metabolism.

1314

## ADVANCE IN MALARIOLOGY

The opportunity has been taken in the annual report of the London School of Hygiene and Tropical Medicine for the year 1946-47<sup>1</sup> to mark the first centenary of public health legislation by including a historical review of the development of public health in Britain from the Public Health Act of 1848 to the operation of the National Health Service Act in 1948. There are, in addition, the usual reports of the activities of each department of the School during the year.

One of the most exciting searches in tropical medicine was successfully concluded at the School when Professor H. E. Shortt and his colleagues discovered the pre-erythrocytic stages of the malaria parasite, both in animals and man. This work closes a chapter in the history of malaria and opens another which may

<sup>1</sup> [For particulars, see Book Reviews, p. 122.]

## EUGENICS: INTELLIGENCE AND GENIUS

Continued from page 78

women, are engaged in one or other of the professional occupations: this is nine times the proportion so classifiable in the general Californian population. Nearly 90% entered college; nearly 70% are college graduates (90 of the group have either taken, or are now working for, a doctorate). Between them the group has published about 90 books or monographs and about 1,500 articles in scientific or scholarly periodicals; and among their number are included

several professors who have won an international reputation. The average income of the male members of the group is \$4,700. Four are earning as much as \$20,000 to \$40,000 a year.

Professor Terman and his colleagues, as well as those who were generous enough to finance his researches, are to be heartily congratulated on the scientific way in which the enquiries have been carried out, and on the success which they have eventually achieved.

well record great advances in our knowledge of the treatment, prophylaxis and immunology of malaria.

During the war, part of the School building suffered bomb damage, and the report mentions the great hindrance caused by the consequent shortage of accommodation in a building in which additional departments are needed. (Reconstruction of the damaged wing commenced in April 1948.)

The year under review saw a record number of entrants (295) to the regular postgraduate courses. The School maintained a full programme of teaching and was able to accept a large number of ex-Service students for the various courses.

The report has obviously been prepared with great care and is as clean and well ordered as the building from which it emanates. It includes some excellent illustrations by Bernard M. Feilden.

L. T. M.

## 1315

## TWO YEARS OF PHYSIOLOGY, 1945-1947

These two volumes, numbers 9 and 10 of the *Annual Review of Physiology*<sup>1</sup>, give a survey of work in physiology, in most cases covering a period from the summer of 1945 to the summer of 1947, although a few articles deal with the literature of several years. Practically every field of physiology finds a mention in these pages, and there is much of interest to the clinician as well. It is possible to enumerate briefly only a few of the interesting topics discussed. In both volumes there is a chapter on the metabolic functions of the endocrine glands, in which the literature on antithyroid drugs and diabetes receives detailed description. Both volumes also contain a great deal of material on peptic ulcer; it is interesting to reflect that some of the 1945 therapy for this malady is already outmoded.

For the surgeon, there are extensive reviews of the literature on shock, with a special chapter in vol. 10 on its metabolic aspects. He will also be interested in the discussion, in the same volume, of haemostasis, with references to fibrin foam and other new stypic agents, and in the chapter on the visceral functions of the autonomic nervous system (vol. 9) in which there is much bearing on the surgery of the sympathetic system. The neurologist is well served, as there are special articles on cerebral electrical activity and experimental neurosis (vol. 9). Both volumes contain an account of the more important new drugs, the latter including the antihistamine drugs, dibenamine and prisco, the newer analgesics, anaesthetics and fungicides, the rickettsiostatic agent *p*-aminobenzoic acid, the chemotherapeutic agents tried in cancer, BAL, the new insecticides, and the rodenticides such as ANTU. Of interest to the haematologist are the chapters in vol. 10 on cytology of the blood, in which folic acid and the chemotherapy of leukaemias are discussed, and on blood coagulation, a subject much in the news recently.

Students of aviation medicine will find valuable data on anoxia in aviation, the effects of changes in barometric pressure (vol. 10) and other aspects of aviation physiology. A note of horror is struck by the detailed abstract of the report by Major Leo Alexander on the experiments at Dachau on effects of cold (vol. 9). Bacteriologists and geneticists are catered for in a discussion of the genetics of bacteria; the immunologist and specialist in infectious diseases should read the chapter on derivatives of plasma, where early work on gamma globulin is described.

An attempt has been made to impart an international flavour to these annual surveys. Though most of the articles are written by American specialists, six British and three authors from the continent of Europe have also contributed reviews. That more European writers are not represented is clearly not the fault of the editors.

## TRICHLORETHYLENE IN CHILDBIRTH

The nineteenth annual report of the Royal College of Obstetricians and Gynaecologists<sup>1</sup> is of special interest in view of the recent discussions, in Parliament and elsewhere, on analgesia

in labour, for it contains (page 59) the report of an investigation made by its Anaesthetics Committee into the use of trichlorethylene as an analgesic in childbirth.

After outlining the scheme of investigation, the report gives details of the types of cases investigated, the efficacy of the analgesia, its effect on the course of labour, on mortality rate, on the foetal pulse rate, and the suitability of trichlorethylene analgesia in the hands of an unsupervised midwife. The apparatus used in all cases was the improved model of the Freedman inhaler.

In the opinion of the Committee trichlorethylene produces adequate analgesia in a high proportion of cases, being superior to gas and air. It can be satisfactorily combined with other analgesics in the more difficult type of labour. A small proportion of mothers become non-co-operative. Evidence of delay due to the analgesic is very slight; there is no sign of increase in the forceps or obstetric interference rate. There did not appear to be any tendency to increased postpartum haemorrhage. A very few cases of cardiac irregularity in the mother were observed, but there was no definite evidence of danger to the mother. The smell is a drawback in some cases and may occasionally cause vomiting.

Although evidence that in certain cases the trichlorethylene was a cause of foetal distress is not very conclusive, one observer considered that it would not be safe in the hands of the unsupervised midwife. Used alone, there was no increase in asphyxia neonatorum, but there was a distinct increase when it was superimposed on pethidine. For use by the unsupervised midwife trained in the method, eight of the observers were of the opinion that it could safely be employed with great benefit to the mother. Two felt that in the hands of midwives without supervision it might be started at an earlier stage and used for longer periods than has commonly been the case in the series under observation, and that further information was necessary; or alternatively, that a slightly weaker mixture of trichlorethylene and air would be more satisfactory. Two observers were definitely against its use without supervision because of its effect on the foetus and production of a non-co-operative state in the mother.

As a result of this investigation, the Council of the College did not consider it possible to recommend the use of trichlorethylene in the Freedman bottle as safe for use by midwives without supervision. Further attempts to produce an apparatus which may fulfil all the requirements for safety will, if successful, enable the Council to reconsider the view it now holds that trichlorethylene is not yet suitable for general use.

## 1317

PUBLICATIONS OF THE  
WORLD HEALTH ORGANIZATION

The publications of the World Health Organization, which include the *WHO Bulletin* dealing with matters of general interest and the *Chronicle* which records the specific activities of the various WHO Committees, have recently been expanded to include the *International Digest of Health Legislation*. Published at the Palais des Nations, Geneva, no. 1 of vol. 1 contains an introduction which gives the historical background of this publication; its existence is an example of the way in which useful work in the international field is being concentrated under the auspices of the United Nations. In July 1946, the duties and functions of the Office International d'Hygiène Publique were transferred to the World Health Organization, and a part of these duties included the publication of a monthly bulletin. The *Bulletin Mensuel de l'Office d'Hygiène Publique* continued publication until December 1946; it was decided that, while the technical reports which had appeared in this *Bulletin* should be incorporated in the *Bulletin of the World Health Organization*, the section devoted to public health legislation should be the subject of a separate publication. The present journal, the *International Digest of Health Legislation*, is therefore the successor to the first section of the *Bulletin Mensuel*.

The *Digest* is published in the English and French languages, and its ultimate scope will be determined by evidence of its utility; unfortunately no indication is given of the intended

frequency of publication. It is hoped to make it a comprehensive collection of the texts of the most important laws and regulations dealing with public health and related subjects in all countries. The present number contains 24 French orders and decrees, with a smaller number from Australia, Belgium, India, the Union of South Africa, and other countries. This publication should be of great use to those interested in the legislative aspects of public health, and should be of considerable assistance to those charged with the revision of existing statutes or the introduction of new ones.

1318

### THE 1948 CHILDREN ACT

The Children Act, 1948<sup>1</sup> is a vital link in the chain of social legislation in Great Britain. Its clauses are based mainly on the recommendations of the Curtis Report (for review see *BMB* 1028). The new Act makes compulsory much of what has previously been done under permissive powers, institutes a measure of control and supervision over children's homes run by voluntary bodies, and, by the appointment of a children's officer to each local authority, co-ordinates the work of various departments in this field.

If a child is deserted or orphaned, or if its parents are unfit or unable to provide proper maintenance, accommodation and upbringing, it is the duty of the local authority to make such provision. This may be done by boarding out in private families or in homes run by voluntary organizations, or by the provision of homes under the direct control of the local authority itself. The Curtis Report revealed the great variations in the standard of children's homes; all these homes are now subject to regular inspection. Permissive power is also given to a local authority to establish hostels for young persons from school-leaving age (15) to 21, near their place of employment, education or training.

The local administration of the provisions of the Act is effected by a specially appointed children's committee to which a "children's officer" shall be directly responsible. This officer plays an important part in the smooth working of the Act, for he is there to provide that personal contact between the State and the individual, the importance of which, though realized, is not always apparent in these bureaucratic days. Appointment of this officer must be approved by the central government and grants can be obtained for training.

This Act came into force simultaneously with the National Health Service Act and already there is evidence that vigorous steps are being taken to implement it.

1319

### FRENCH MEDICAL SCIENCE: A NEW ENCYCLOPAEDIA

After the First World War, the now well-known *Nouveau traité de médecine* was published under the direction of MM. Roger, Vidal and Tessier. It encompassed French medical thought and teaching and provided an authoritative reference work for students and practitioners; it established a tradition of authority for French-speaking medical men and women everywhere. The advances of medicine in every field during the intervening period have made satisfactory revision of this work impossible. A completely new work was necessary; and as the result of the labour of a distinguished group of French medical scientists a new *Traité de médecine* has been planned and publication is now almost complete.

The responsible committee, A. Lemierre, C. Lenormant, P. Pagniez, P. Savy, N. Fiessinger, L. de Gennes and A. Ravina have had the collaboration of a large number of distinguished medical and surgical colleagues; the work can truly claim to be an authoritative presentation of current French medical thought. The complete work will comprise seventeen large volumes, fifteen of which we have already received. The first four deal with infectious diseases, cancer, avitaminoses, allergic diseases and diseases due to physical agents; the remaining volumes are arranged on a systematic basis. It is the aim of the work to

provide very full information concerning the scientific background of clinical medicine, together with adequate practical information concerning therapy. The firm of Masson & Cie can take great pride in the completion of such an ambitious project; we hope to give a fuller account of this work in a later number of the *British Medical Bulletin*.

D. F.

1320

### ENGLISH FOR SPANISH-SPEAKING DOCTORS AND MEDICAL STUDENTS

Messrs. Longmans, Green & Co., London, have just published a small book designed to help the medical man in Spanish-speaking countries to acquire rapidly a working knowledge of English, with special reference to medical texts. This book, which should fill a long-felt want, consists of 24 short lessons, and when these have been mastered the reader is in possession of a remarkably wide vocabulary of medical terms in daily use. The book is reviewed in Shorter Notices (*BMB* 1406, p. 130) in this issue.

1321

### SOME MEDICAL CONGRESSES

We have received notice of the following meetings:

A Conference on Pneumosilicosis will be held in Sydney, Australia on 28 February 1950. Information regarding this meeting may be obtained from the Dean, School of Public Health and Tropical Medicine, University of Sydney, Australia.

\* \* \*

At the Hotel Statler, New York, the International Congress on Obstetrics and Gynaecology will be held from 14-19 May 1950. The subjects to be discussed will include physiology and pathology of human reproduction, social and economic problems, neoplastic diseases of the female reproductive system, and obstetric and gynaecological procedures. Further information may be had from Dr. Fred L. Adair, 24 West Ohio Street, Chicago 10, Illinois.

1322

### PUBLICATIONS AND REPORTS

The report of the governing body of the Lister Institute for the year 1948<sup>1</sup> records the death of Professor J. McIntosh, a member since 1931, and the retirement of Dr. Muriel Robertson. Details are given on the progress of the bacteriological, immunological, pathological, biochemical, biophysical, physico-chemical, and nutritional studies which were continued during the year, and reports are included on the work done by the Medical Research Council external staff and the Ministry of Health. A list of scientific papers published from the laboratories during the year concludes the report, which appears above the signature of Sir Henry Dale, chairman of the governing body. So much work is recorded in this short report that it is well worth examination, as giving a representative picture of laboratory investigation in Britain today.

\* \* \*

We have received for the first time one of the publications (no. 73, 1948) of the Misión de Estudios de Patología Regional of the University of Buenos Aires. The Misión has for the past 20 years been engaged in field studies in epidemiology and in carrying out laboratory tests and diagnoses for Argentinian doctors. The present publication contains articles on the distribution of Chagas' disease (Dr. Alberto E. Manso Soto), on diagnostic methods in brucellosis (Drs. Alberto E. Manso Soto & José A. Rispoli), on mosquitoes of the city of Buenos Aires (Drs. Alberto E. Manso Soto & Antonio Martínez), and a cytological study of plasmocytes (Dr. Guido A. Loretí). This number is well printed on art paper and illustrated with photographs in monochrome and colour.

<sup>1</sup> [For particulars, see Book Reviews, p. 123.]

Boletim 81 (Estatística, no. 2) of the Faculty of Philosophy, Science and Literature in the University of São Paulo has reached us. This is a detailed biometrical study of 20,852 secondary school children, aged 11–19 years, in São Paulo, carried out by the Professor of Statistics, M. da Silva Rodrigues. There is a full summary in English.

\* \* \*

Under the general title *Conferencias Magistrales*, the Hospital Municipal de Infecciosos, Barcelona, has issued as vol. 8 (1948) of its series of publications the Spanish version of the lectures delivered by Sir Alexander Fleming in May–June 1948, when he visited Barcelona at the invitation of the hospital. Publication has been subsidized by the Instituto de Biología y Sueroterapia, Madrid.

The lectures were delivered in English and simultaneously, re-transmitted in Spanish to audiences in other halls. The subjects chosen were "Some problems of a septic wound," "Lysozyme", and "The use of penicillin". Photographs illustrate the text. The volume also contains an address delivered by Sir Alexander at the inauguration of the hospital's research department.

1323

## NEW JOURNALS

Probably as an aftermath of the war, new journals continue to appear in, one might say, alarming number. Of the score of journals noticed below some are the organs of recently formed associations, as, for example, the *World Medical Association* and the *World Federation for Mental Health*; some pertain to fields of enquiry, now much extended, such as *aviation medicine* and *experimental psychology*; a few are old friends in a new guise, refurbished, enlarged and generally improved.

The International Congress on Mental Health held in London in August 1948 issued a series of twelve bulletins dealing with the progress of its work; these now have a permanent successor in the shape of a bi-monthly *Bulletin of the World Federation for Mental Health* (London, 5s. per annum). The number received gives prominence to articles and news on the work of UNESCO and WHO. Dr. Jaime Torres Bodet, Director-General of UNESCO, contributes an article on current misunderstandings of the statement in the preamble to UNESCO's constitution which reads: "... since wars begin in the minds of men, it is in the minds of men that the defences of peace must be constructed". Dr. Otto Klineberg, of the Department of Social Sciences, UNESCO, writes on "UNESCO Community Studies". The methods to be followed in these studies were discussed at a conference in Paris in January 1949, noticed on another page of the *Bulletin*. The 1950 mental health programme of WHO is outlined in a press release. The text of the Universal Declaration of Human Rights adopted by the United Nations General Assembly is reproduced in full, with part of a covering letter from Dr. Jaime Torres Bodet. Notices of forthcoming international conferences, news of the activities of the World Federation and its member associations, and details of the published Proceedings of the 1948 International Congress make up the remainder of this *Bulletin*, which has condensed a remarkable amount of matter into small compass.

*Journal of Pharmacy and Pharmacology* (London), vol. 1, no. 1, 1949. This is the successor to the *Quarterly Journal of Pharmacy and Pharmacology* and is published monthly, in a new format, by direction of the Council of the Pharmaceutical Society of Great Britain. Several new features have been added: these include a regular review article written by an expert in a particular field of pharmacy or pharmacology, a book-review section, and an enlargement of the section devoted to abstracts of current pharmacological literature. The new journal is more attractively

presented and slightly larger in page size than its predecessor; its publication should be attended by a well-deserved success. The annual subscription is £2.

*The Medical Bookman and Historian*, which commenced publication in 1947 and has already been noticed in these columns (see *BMB* 1219), has now been incorporated in *Medicine Illustrated*, the volumes being numbered in continuation. This new publication, while still devoting some space to the historical aspects of medicine, will include clinical articles, especially those calling for illustrations. It is a beautifully produced journal, lavishly illustrated, and a credit to British printing. The reproduction of the illustrations attains a high standard. The first number contains four clinical articles, some contributions to the history of medicine, and a number of authoritative book reviews.

\* \* \*

There has been a large increase in the volume of work done in the general field of psychology in Great Britain in recent years, and up to the present there has been no journal devoted exclusively to the publication of the results of laboratory and scientifically orientated clinical studies. We have received vol. 1, part 1 of the *Quarterly Journal of Experimental Psychology*, which seeks to remedy this defect. Produced under the auspices of the Experimental Psychology Group—a small private society whose membership is drawn from the teaching and research staffs of British universities and research institutions—it will be open to contributors from any country. The annual subscription is £1 10s. net per volume. The journal is carefully edited and well produced.

\* \* \*

The newly organized Réseau de Lutte Anti-Cancéreuse en Algérie has begun publication of the *Bulletin Algérien de Cancérologie* (Algiers), which is to appear three times a year. Its aim is to assemble all North African writings on cancer and bring about an exchange of ideas among workers in this field. The number received (vol. 1, no. 1, 1948) contains the proceedings of the first and second Algerian conferences on cancer, November and December 1947, and a section of references and abstracts of work on cancer published in French North Africa since 1 January 1940. This section is to be a regular feature and is designed eventually to cover all the French colonies. A third section contains general news and anti-cancer propaganda.

\* \* \*

*Revista de Sanidad de Aeronáutica* (Buenos Aires) appears under the authority of the Argentine Air Ministry. It is to be published quarterly. Vol. 1, no. 1, March 1948, which we have received, contains articles on the importance of perfect masticatory function in flying personnel (Carlos A. Chavarri & Alejandro Ramos Majía); on cardiovascular function at great heights (F. Plas, L. Tabusse, A. Missenard & C. Goujon); on the treatment of burns in aviation medicine (R. Agrelo); an ointment for use in such treatment (Miguel J. Larumbe, Anibal R. Caccia & Luis A. Carbone); and the organization of a laboratory of dental prosthesis (Armando G. Casalins).

\* \* \*

The University of Cochabamba, Bolivia, has begun the issue of *Folia Universitaria*, to be the medium of publication for results of research by the University staff. Vol. 1, no. 1 (December 1947) includes an article on the renal index of acidosis as an expression of renal functional activity; the authors are Dr. Santiago Pi Suñer, professor of normal and pathological physiology, and Srta Elsa Selemé Vargas, assistant in the department of physiological chemistry. Other sections in this number are devoted to archaeology, entomology and botany.

\* \* \*

*Revista Brasileira de Cancerologia* (Rio de Janeiro) is the official quarterly journal of the Serviço Nacional de Câncer, instituted in 1941; publication begins with the number we have just received (vol. 1, no. 1, September 1947). Its aims are to make the work of the S.N.C. known to all practitioners in Brazil and to enlist their interest in the problems of cancerology, with special emphasis on the matter of early diagnosis. The present number includes articles on the time factor in roentgenotherapy (Dr. A. Ozório de Almeida), present-day standards in the treatment of cancer of the breast (Dr. Antonio Prudente), cancer and pregnancy (Dr. Mário Kroeff), and radiotherapy of cancer of the lip and tongue

(Dr. Nelson Carvalho). Case-reports, shorter articles, abstracts from current periodicals, and a report of a meeting of the Sociedade Brasileira de Cancerologia make up the rest of the number, which is illustrated with photographs. Two of the main articles have summaries in English.

A new journal from Bogota is the monthly *Boletín del Instituto Nacional de Radium*. The editors intend that it shall consist of two parts, a clinical section presenting notable cases seen by the Institute, and a section of original contributions and reports of lectures. In vol. 1, nos. 1 and 2, 1948, cases are reported of cyst-adenoma of the breast simulating sarcoma, molluscum pendulum, and cancer of the larynx treated surgically; two original articles (both by Dr. Luis M. Borrero) deal with general considerations on x- and γ-rays, and general methods and biological bases of radiotherapy; others deal with naso-pharyngo-sinusal cancer (Dr. Roberto Restrepo), and tumours in general and classification of tumours (Dr. Alfonso Méndez L.). The *Boletín* is well printed and adequately illustrated with drawings and photographs.

Also from Bogota is *Revista del Hospital de la Samaritana*, of which we have received vol. 1, no. 2, October 1948. This new quarterly is the organ both of the Hospital and of the Instituto de Higiene Social de Cundinamarca. All contributions to this number are by members of the hospital staff, and deal with latent syphilis (Dr. Jorge Cavelier), syphilis congenita tarda (Dr. E. Quintero Cañizares), treatment of burns (Dr. G. Nieto Cano), duodenal intubation (Dr. E. Peña Alvarado), the Mazzini microscopic serum flocculation reaction (Dr. F. Cortés Boshell), liver extract (Dr. G. Escallón Caycedo), and demerol (Dr. A. Felfie). The editorial makes proposals for control of laboratories which carry out serum reaction tests for syphilis.

*Boletín del Hospital Militar* (Havana), of which we have received vol. 1, no. 1, July 1948, is a new quarterly consisting entirely of selected items from the weekly clinical and scientific meetings of the staffs of the Hospital Militar "Dr. Aristides Agramonte" and of the Clínica Central "Dr. Carlos J. Finlay". In size and format it resembles the well-known *Proceedings of the Staff Meetings of the Mayo Clinic*. It is illustrated with photographs, and some of the articles are accompanied by summaries in the original language.

The conditions of war made it impossible for Les Sociétés d'Obstétrique et de Gynécologie de France to publish their Bulletin from 1940 until January 1949. We have received vol. 1, no. 1 of their new publication, *Bulletin de l'Association des Gynécologues et Obstétriciens de Langue Française*. Published in Paris, five numbers will appear annually; as the name implies, the new publication has enlarged its scope and its pages will record the activities of the societies which together compose L'Association des Obstétriciens et Gynécologues de langue française, la Société Royale Belge and La Société de la Suisse Romande. The present issue reports the proceedings of a considerable number of the meetings of the member societies; there is in addition a large section devoted to abstracts of current literature of the specialties.

*La Chronique Médicale de la Bigorre* (Tarbes) is a new venture—a journal of professional news emanating from the provinces but directed not only to local doctors but to colleagues all over France and even to those outside that country, with the hope of establishing contact and exchange of views between widely separated medical men. While this seems a worthy object, we cannot help feeling it is a little ambitious. We recognize the value of optimistic idealism and the fact that great things may grow from small beginnings, but, in its first three numbers (nos. 1, 2 and 3 for January, February and March 1948 respectively), this slight journal has a light-bearded and somewhat irresponsible air strongly reminiscent of an English medical school magazine—excellent in its place, but hardly calculated to enhance serious professional relations on the international plane.

The first two numbers (vol. 1, fascicles 1 and 2, March and July 1948) have reached us of a new Italian quarterly of general medicine entitled *L'Arcispedale S. Anna di Ferrara*. The March number opens with an outline account by Professor Galavotti of the administrative history of the hospital since its foundation by Papal decree in 1440. He sets out the stages by which it

attained the title "Arcispedale", as late as the second half of the 18th century. Professor Galavotti hopes to deal with the medical history of the hospital in a later article. Other articles cover a wide field of general medicine, pathology and minor surgery. By an editorial directive, all articles have summaries in Italian, French, English and German.

*Minerva Pediatrica* (Turin) is a new Italian monthly specialist journal, uniform in style with the well-known *Minerva Medica*. It combines three journals formerly published by Edizioni Minerva Medica: *Medicina Italiana*, *Pediatria del Medico Pratico*, and *Policlinico Infantile*. Vol. 1, no. 1 (January 1949) contains an address on inoculation against tuberculosis, by Professor G. de Toni, and articles on the relative concentration of penicillin in blood and cerebro-spinal fluid (Dr. M. Gomirato Sandrucci), on a method of making megacaryocyte counts in infants (Drs. E. Grasso & C. Sticca), applications of radioactive isotopes (Dr. C. Lombroso), Hand-Schüller-Christian's disease (Dr. F. Toscano), and the toxicity of streptomycin (Dr. C. Fuà). Most of the longer articles have summaries in the original language. A short section of abstracts from non-Italian periodicals is included.

Vol. 1, no. 1 (May-June 1948) of the bimonthly *Revista del Instituto Mexicano para el Estudio y Tratamiento de los Tumores* contains articles on carcinoma of the prostate (Drs. C. P. Mathe & Carlos E. Ardila), on biopsy (Dr. Alvin G. Foord), on clinical aspects of mammary cancer (Dr. G. Vázquez Arroyo), on the role of histopathology in the anti-cancer campaign (Dr. J. Sánchez Márquez), and on cancer investigation in France under the guidance of the Institut National d'Higiène (Dr. P. Denoix). Most of the articles have summaries, in the original language.

We have received vol. 1, no. 1 (November 1948) of the *Pakistan Medical Journal* (Karachi)—apparently the only regular medical publication in Pakistan at present. The auspices under which it is being published are not entirely clear, but it is apparently getting a good deal of financial support from the Asian Laboratories Limited, manufacturers of pharmaceutical products in Karachi. The main articles are not of a very high scientific standard, and contain little of significance; this is perhaps because they are largely reports of medical addresses rather than the result of clinical study or research work. Typographical errors abound, and the journal is not well produced. A medical journal of high standard would be of enormous value to Pakistan, and it may be that with further experience this one will fill the need. The editorial policy advocates the teaching of medicine in Urdu, and the preservation of the Unani system of medicine fused with modern scientific knowledge. The present journal, however, is entirely in English. The foreign rate of subscription is £1 6s. per annum.

*Gazeta Médica Portuguesa* (Lisbon) is a new quarterly designed on a comprehensive scale. The present number, of 258 pages, (vol. 1, no. 1, 1948) is made up of 19 sections: medicine, surgery, pathological anatomy, cardio-angiology, dermatovenereology, gastro-enterology, haematology, hygiene, neurology and psychiatry, paediatrics and puericulture, phthisiology, stomatology, obstetrics and gynaecology, opthalmology, oto-rhino-laryngology, orthopaedics and traumatology, urology, clinical analyses, and nursing. Sections on pharmacology and therapeutics, radiology, and legal medicine are announced for inclusion in the next number. The editors state that each section is regarded as an independent review, which may be bound in five-yearly volumes; accordingly, there is a sectional pagination as well as one for the whole number. Most sections include reviews of selected articles in their own field. In addition, a separate section of reviews is to be included in future numbers. The journal is illustrated with photographs and drawings, and nearly all the original articles have summaries in English and French.

Vol. 1, nos. 2 and 3 (March and June 1948) of *Archivos del Colegio Médico de El Salvador* (San Salvador) have reached us. The Colegio has now taken a leading place in a federation of Salvadorean medical societies (Federación Médica Salvadoreña), formed in May 1948. The *Archivos* are published quarterly. Most of the original articles are followed by a summary in Spanish. No. 3 includes details of a social security scheme drawn up by a government-appointed commission, covering

medical and dental services and maternity benefits as well as provision for unemployment, etc. Abstracts from American and British periodicals form a separate section.

From Spain we have received *Ciencias Médicas Hispano-Americanas* (Madrid, vol. 1, no. 1, 1948). This new journal is to be issued annually by Editorial Médica "Made". The first number contains interesting articles on a variety of subjects, including an account of the Spanish influenza epidemic during the winter 1946-47 (Dr. M. Bañuelos), a clinical history of a case of synovial osteochondrosis (Dr. Otero Sánchez), physio-pathological observations on arteriovenous aneurisms (Professor P. Piulachs), and a study of the problem of arseno-resistants in syphilis by Dr. Sáinz de Aja. In addition to original articles, the journal contains a section on medicine and art, obituary notices, notices of meetings, and news and abstract sections.

The World Medical Association, formed in 1946, has begun publication of a quarterly *World Medical Association Bulletin* (Mount Morris, Illinois). Contributions are published in English, French, and Spanish; the more important ones appear in all three languages, printed in parallel columns. Vol. 1, no. 1 (April 1949) is mainly concerned with the ethical basis of medicine. A statement on "War Crimes and Medicine" discusses measures for the moral rehabilitation of the German medical profession in world opinion; in the same article a revised form of the Hippocratic oath is proposed for adoption by universities and licensing authorities. J. Voncken in another article suggests that such an oath would best be administered under the authority of the Permanent International Court of Justice, which would have the power to prosecute and punish perjury. Dr. T. C. Routley, General Secretary of the Canadian Medical Association, writes on the aims and objects of the World Medical Association. In a preliminary report on social security adopted by the General Assembly of the World Medical Association, twelve principles are enunciated which should govern the provisions of medical care where this forms part of a scheme of social security. The number closes with a general report on the second annual meeting of the General Assembly in September 1948, and an announcement of the next meeting of the General Assembly, to be held in London in October 1949.

A new specialist publication from Venezuela is *Archivos Venezolanos de Patología Tropical y Parasitología Médica* (Caracas), of which we have received vol. 1, no. 1, January 1948. This journal is edited in the Department of Tropical Pathology of the Universidad Central de Venezuela, and is published with the collaboration of the Fundación Biogen, Caracas. The present number consists entirely of ten original articles; these include contributions on the first determination of *Trypanosoma rangeli* in the human organism from a culture of peripheral blood (Dr. Félix Piñano C. and others), experimentally produced unisexual infection by *Schistosoma mansoni* (Dr. Félix Piñano C.), treatment of bilharziasis with preparations of antimony (Professor Martín Mayer), and synthetic anti-malarial drugs (Drs. S. Holz & M. Granier). The other articles consist of studies of tropical disease in Venezuela. Summaries, usually in English as well as in Spanish, accompany all articles; most are of adequate length, but a few should be much fuller in order to be worth while. The journal is illustrated with drawings, graphs and photographs; unfortunately the poor quality of paper used makes it difficult to assess the value of the latter.

1324

## JOURNALS NEWLY RECEIVED

The *British Journal of Urology* (London), vol. 21, no. 1, March 1949, appears in an attractive new format and under new editorial direction. The number and length of main articles has been increased; these are profusely illustrated, and the quality of the illustrations, x-ray reproductions, and diagrams is very high. There is also a comprehensive "Index to Current Urological Literature" which should prove extremely useful. The journal maintains in every way its former high standards, and is a publication worthy of representing the British Association of Uro-

logical Surgeons. The annual subscription is £2 2s. per annum; the journal appears quarterly.

*Parasitology* (London) has long been a standard publication in its field, and its presentation and reproductions are above reproach. We have recently received no. 1-2 of vol. 39, and this, with subsequent numbers, will be available in the Medical Department library of the British Council. Cambridge University Press are the publishers of this journal, and its subscription rate is £2 15s. per volume.

We have recently received vol. 26, parts 1-6, 1948 and vol. 27, part 1, 1949 of the *Australian Journal of Experimental Biology and Medical Science*. This bimonthly journal, published by the University of Adelaide and managed by the Medical Sciences Club of South Australia, has, for more than twenty years, been devoted to the prompt publication of the results of Australian medical research. Its field of interest includes the whole range of the medical sciences, including zoology, genetics, and animal and plant physiology. It is restricted almost entirely to Australian work, and is well produced and carefully edited.

The *Patna Journal of Medicine* is an English language Indian medical publication issued quarterly and chiefly devoted to problems of public health and social medicine as well as to general clinical topics. The present issue (vol. 22, no. 1-2, January-April 1948) displays great interest in the National Health Service of Great Britain and gives a considerable amount of space to it. With the present changes in India there will be an expanding field of useful activity for such journals.

*Revista de la Asociación Argentina de Venerología y Profilaxis Social* (Buenos Aires) is now in its 13th year of publication. This journal publishes, mainly, articles specially written for it, or the text of lectures and discourses delivered at the meetings of the Association. The first number received here was vol. 11, no. 19, 1947; this opens with an article inaugurating a series by Dr. Alejandro Dicosky which studies the social implications of venereal diseases. Summaries of discourses delivered by delegates at meetings of the Association are also included, as well as the text of lectures given at its 34th scientific session in May 1947. In addition, the journal contains a section giving news of appointments and retirements and a general news section.

*Anais do Instituto Pinheiros* (São Paulo), vol. 11, no. 22, July 1948, contains articles on nitroglycerine (Dr. V. Van der Reis), salmonellosis of guinea-pigs (Dr. Arnaldo A. Pereira and others), and on South American blastomycosis (Dr. C. S. Lacaz); summarized proceedings of the meetings of the Council of the Institute, and a short section of book reviews. The journal is illustrated with photographs, charts, etc., and the table of contents appears in English as well as in Portuguese.

An exchange has been arranged with *Revista de Medicina e Cirurgia de São Paulo*, the monthly journal of the medical and surgical society of São Paulo. The first two numbers received (vol. 8, nos. 1 and 2, January and February 1948) contain articles on the statistics of the acute abdomen in gynaecology (Dr. Hilda Paonessa), the problem of exposure of recurrent nerves in thyroidectomy (Dr. S. Hermeto, jr.), and the milk trade in São Paulo from the point of view of social hygiene (Dr. F. Pompêo do Amaral). Brief notes of the meetings of the Sociedade de Medicina e Cirurgia de São Paulo appear in the February number.

A special number of *Archivos de la Sociedad de Cirujanos de Hospital* (Santiago), 1948, is devoted to the proceedings of the ninth Chilean congress of surgery held in Valdivia in December 1947. Symposia on blood proteins in surgery, osteomyelitis, and rectal prolapse, and 22 papers on miscellaneous subjects, are included. All contributions are fully reported, in the usual style of this journal; the majority are illustrated, with summaries in the original language and bibliographies.

*Revista de Medicina y Alimentación* (Santiago) is published quarterly by a group of scientists drawn from Argentina, Chile and Peru. Vol. 8, no. 1-3 (January-April-June 1948) contains

an account of a clinical trial of streptomycin with para-aminosalicylic acid in a case of pulmonary tuberculosis (Dr. Arturo Rodríguez R.), and six studies in nutrition, concerning proteins in nutrition (Dr. Julio V. Santa María), consumption of fish in Santiago (C. Leyton G.), administration of amino-acids to premature infants (Dr. E. Zarzar Miquel), prevention of dental caries in children by the use of bone salts (Dr. A. Fernández Correa & Sr. Carlos Doer Z.), concentrated vegetable soup in infant feeding (Drs. A. López Matas & F. Mardones Restat), and the protein quota in the diet of a section of the population in Santiago (Dr. R. Miranda and others). The longer articles have summaries in Spanish.

Published in the same cover with the *Revista* is the *Boletín de la Sociedad de Biología de Santiago de Chile* vol. 6, no. 1, October 1948) containing reports, many of which are in full, of papers read before the society.

*Boletín de Sanidad y Asistencia Pública* (Ciudad Trujillo), of which we have received vol. 4, nos. 1 and 2, January-March and May-June 1948, is the quarterly journal of the Ministry of Health and Public Assistance of the Dominican Republic. Each number contains a full summary of new national legislation in these fields. In addition, no. 1 contains an article on the contribution of British medicine to the progress of world medicine, by Dr. J. Jaramillo-Aranga, former Colombian Ambassador in London, and no. 2 an article on the World Health Organization, by Dr. H. Van Z. Hyde, and another by Dr. Corwin Hinshaw on the present state of streptomycin investigation; this latter is reproduced from the *Boletín de la Oficina Sanitaria Panamericana*.

*La Parfumerie Moderne* (Lyons) is a bimonthly technical journal of the perfumery industry, which publishes articles of a scientific nature, many of them having a medical bias. The number for June 1947 (year 39, no. 4) is a special number on the practice of cosmeticology. There are six main articles on such subjects as the use of protein hydrolysates in nutrition of the skin, and the new American emulsifiers derived from sorbitol. The number also includes reports on two congresses (the Congress of Cosmeticology, held in Paris in June 1947, at which a paper was read by Dr. J. M. L. Burtenshaw, then Scientific Adviser to the British Council in Paris, and the Congress of Pure and Applied Chemistry, held in London in July of the same year); one book review (of *Modern cosmeticology*, by R. G. Harry, London, 1946); and an article on cosmeticology for summer holidays (formulae of the preparations recommended are given). In addition, three and a half pages are devoted to a critical analysis of vol. 1, no. 4 of the French edition of *BMB* (corresponding to vol. 3, no. 7-8, "Skin and its Disorders", of the English edition), the greatest attention being given, as would naturally be expected, to the article by Berry on ointment bases (*BMB* 737).

*Zeitschrift für Hygienische Zoologie und Schädlingsbekämpfung*, now in its 37th year, deals with parasitology and with pest destruction in its widest sense. It aims to bridge the gap between theory and practice and to make available the information required to apply the newer methods of pest destruction. The journal, published by Duncker & Humblot of Berlin and Munich, now resumes publication, having been suspended in September 1944. No. 1, January 1949, largely concerns itself with communal methods of rat destruction, malaria control, and the uses of DDT.

An exchange has been arranged with the well-known Italian bimonthly journal, *Lotta contro la Tuberculosis* (Rome), the organ of the Federazione Italiana per la Lotta contro la Tuberculosis. We have received nos. 1-3 of vol. 18 (January-February to May-June, 1948). Nos. 1 and 2 include four articles on tuberculosis in Italy in relation to the war and the post-war period; these deal with the causes, frequency, mode of onset and course of pulmonary tuberculosis in Italy during and since the war, with special reference to Venetia Tridentina, by Professor Vittorio Lubich; the course of pulmonary tuberculosis during and since the war, with special reference to specific peritoneal, gastric and intestinal complications, by Dr. F. Enrico; pulmonary tuberculosis in Bolzano during the war and the post-war period, by Professor Mario Martinelli; and the mortality from tuberculosis in Italy during and after the war, by Giovanni L'Ellore and Elio Caranti. The first three papers were presented at the second

scientific convention of the Associazione Regionale Tridentina contro la Tuberculosis, held at Arco in September 1947; a full summary of its other proceedings appears in the March-April number. No. 3 (May-June) contains the programme and six papers for the seventh national anti-tuberculosis conference, to be held at Bari in October 1948. Owing no doubt to present-day difficulties, these numbers bear a date considerably earlier than their actual date of issue—e.g. the March-April number finished printing at the end of August 1948.

*La Medicina del Lavoro* (Milan). We have received for the first time a number (vol. 39, no. 1, January 1948) of this monthly periodical. The original articles included deal with a fluorographic survey of silicosis and tuberculosis among insured workers in North Italian foundries and steel works (Professor Enrico C. Vigliani, Drs. Luigi Parmeggiani & Ennio Zanetti); a radiological study of the hilar shadows of 1,026 sufferers from silicosis (Dr. Ennio Zanetti); a histological study of the central nervous system in a case of acute CO intoxication (Dr. Carlo Ceresa); and a study of symptoms of chronic intoxication in workers engaged in nitrobenzene and dinitrobenzene production (Dr. Cornelio Bellesini). Each article is followed by a summary, which in most cases appears in English also. Reviews of books and selected articles, and a section of notes and news, are also included. The journal is well produced, its appearance showing little trace of repercussions from post-war difficulties or shortages.

From Mexico comes the *Anales de la Sociedad Mexicana de Oftalmología*, 5th series, vol. 22, no. 3, July-September 1948. Articles in this number deal with Romberg's disease (T. Agundis, jr.), epithelial oedema of the cornea (David G. Cogan), fractures of the orbit (Raúl A. Chavira), and the thesauruses (E. González Aguilar). Illustrations and very brief English summaries are included.

We have received vol. 7, 1947-48, of *A Criança Portuguesa*, bulletin of the Instituto António Aurélio da Costa Ferreira, Lisbon, a government-aided foundation for the study, practice and teaching of child psychiatry. The institute admits backward and problem children of all categories for observation, and advises on their future treatment or training in homes, special schools, out-patient clinics, etc.; it also provides out-patient consultations and a domiciliary visiting service, and courses of instruction for teachers and social workers. During the period 1942-1947, 2,149 children were seen; in December 1947 more than half this number were still awaiting vacancies in suitable institutions.

Vol. 7 of *A Criança Portuguesa*, which is published complete (468 pages), contains 12 original articles, a section devoted to reports of congresses, a report on the work of the institute and a section of book reviews. Dr. V. M. Santana Carlos, director of the Albergaria de Lisboa, a training school for backward children, contributes an account (160 pages) of training institutions and after-care for mentally deficient children in Belgium, Denmark, Spain, Holland, England, Italy, Sweden and Switzerland. The material for this was gathered during a three months' study tour. Other articles which illustrate the international outlook of this bulletin are: "Modern Trends in Child Guidance in the United States" (Mlle. C. Arnou, in French), and "The Care of Mentally Backward Children in Sweden" (Torsten Ramer, in German). All articles have full summaries in English, and in French, unless themselves written in French. The bulletin is illustrated with photographs, unfortunately not very well reproduced; apart from this it is well printed, and its unusually handy size (23 x 16 cm.) is a very agreeable feature.

The monthly *Boletín Cultural e Informativo* (Madrid) of the Consejo General de Colegios Médicos de España, of which we have received vol. 5, nos. 23 and 24 (October and November 1948) is made up of a number of regular features: each number includes one article on medicine, surgery, therapeutics, a special subject, literary aspects of medicine, sickness insurance, and photographs of some particular institution, as well as general medical news, and changes of address of practitioners in Spain. An interesting feature is a sheet of abstracts from Spanish periodicals, printed on stiff paper in semi-perforated "boxes" measuring 12 x 7 cm., designed for filing in a card cabinet.

The following journals have also been received :

### British

- Mental Health* (London), vol. 8, no. 3, 1949  
*Mouth Mirror. The Journal of the Incorporated Dental Society* (London), vol. 22, no. 174 & 175, 1948  
*North Wing. The Magazine of the Sheffield Medical and Dental Schools* (Sheffield), summer 1948  
*Prescriber* (Edinburgh), vol. 42, no. 1, 1948  
*Rehabilitation* (London), no. 1, 1948

### European

- Acta Anatomica* (Basel), vol. 3, no. 3-4, 1947  
*Acta Medica* (Izmir), vol. 1, no. 2, 1948  
*Annales Médicales. Revue de l'Union des Médecins Bulgares* (Sofia), year 40, no. 1, 1948  
*L'Année Biologique* (Paris), vol. 24, no. 1, 1948  
*Biologické Listy* (Prague), year 28, no. 3, 1947

### EDINBURGH AND MENTAL SCIENCE

Edinburgh's contributions to surgery and medicine are well known. Not so familiar, yet significant if less considerable, is her part in psychiatry.

Lectures in mental diseases have been given in Edinburgh since 1823.

It is doubtful if the subject has been taught for such a long unbroken period in any other medical school in the world. Although Esquirol was the first in 1817 to give regular lectures in Paris, his lectures came to an end about eight years afterwards. It may be said truly that the Edinburgh Medical School and not that of Paris inherits his tradition.<sup>1</sup>

Indeed, earlier than 1823, when the Royal Asylum was built at Morningside, Edinburgh (under an Act<sup>2</sup> which also covered the use of British fisheries!), instruction in mental diseases to students was considered, as well as the care of inmates. Subscriptions for this asylum came from all over the world—Madras, for instance, contributed £1,000.<sup>3</sup>

The first course of lectures in mental diseases was delivered by Sir Alexander Morison, to whom the idea of such instruction arose from his visit to Paris. The university authorities at Edinburgh were not sympathetic to the suggestion of founding a chair of psychiatry—Professor Hope, discoverer of the maximum density of water, saying that the university would be having a lectureship in dropsy established by some gouty old gentleman or accepting a lectureship in pleurisy, if they were not careful—so Morison delivered the lectures privately. His first audience numbered six. He continued these annual lectures until 1852<sup>4</sup> and published several books on psychiatric subjects.<sup>5</sup>

In 1859 Thomas Laycock (1812-1876), Professor of Medicine, introduced a summer course of lectures on medical psychology; they were delivered to "a limited but thoughtful class of students." Laycock was "a voluminous writer, a philosophical thinker, and a man of immense erudition."<sup>6</sup> His doctrine of the reflex functions of the brain he first began<sup>7</sup> to formulate when at York; his last paper on the subject appeared in the *Journal of Mental Science*

shortly before his death in 1876.<sup>8</sup> His treatise, *Mind and brain* (Edinburgh, 1860), published when he was Professor in Edinburgh, prepared the way for the study of unconscious cerebration, to which he afterwards chiefly devoted himself; the phenomena which he described only received full recognition in connexion with nervous cases observed in the First World War. He also published *Nervous diseases of women* (London, 1840).<sup>9</sup>

The first Lecturer in Mental Diseases at Edinburgh University was Sir Thomas Smith Clouston (1840-1915), whose *Clinical lectures on mental diseases* (London, 1883) was a standard textbook.<sup>10</sup> On the scientific side he advocated a somatic classification of insanity. He was particularly concerned for "the establishment of an atmosphere in which no more stigma should attach in the public mind to the incidence of an attack of mania than to an attack of measles, and to that end he set himself to instil his views into the medical mind, and through it to influence the public. Hence the popular strain in which his well-known textbook was written, and hence his efforts to adapt asylums and their administration to medical conceptions of the treatment of disease."<sup>11</sup> To this end, too, Clouston devoted the latter part of his life to public lecturing and wrote two books for the layman, *The hygiene of the mind* (London, 1906) and *Unsoundness of mind* (London, 1911). He "foreshadowed the present-day vogue for popular expositions of psychology."<sup>12</sup> Nor must one omit to mention that he was the first to advocate training for what were then called "asylum attendants." This he suggested in an address to the Royal Medico-Psychological Association in 1876.<sup>13</sup> Later, the Association established the first national examination for nurses in the mental field.

Sir John Batty Tuke (1835-1913), who was appointed lecturer in psychiatry in the School of Medicine of the Royal Colleges (Surgeons' Hall), Edinburgh, in 1874, was the first to describe what are now known as senile plaques, and the pigmentary deposits in the vessels and cells of the cerebral cortex. "He was a man who allowed no liberties to be taken with him, was a trifle irritable at times, and always kept up the dignity of his profession." He influenced modern psychiatry,<sup>14</sup> and was one of the first to abolish mechanical restraint.<sup>15</sup>

Another pioneer in humane treatment was also associated with Edinburgh, having received his medical education there. He was Dr. Alexander Francis Browne, who introduced at the Crichton Royal as early as 1844 theatricals and concerts and a monthly

magazine, all produced by the patients. Dr. Browne's son, Sir James Crichton-Browne, was also educated at the Edinburgh medical school; he established at Wakefield the first research laboratory in neuropathology in the United Kingdom and was one of the first to stress the importance of early recognition and treatment of breakdown.<sup>10</sup>

Robert Whytt (1714-1766) in 1751 published an *Essay on the vital and other involuntary motions of animals* (Edinburgh), which contains a record of numerous experiments dealing especially with reflex movements. He also was the first to give a clear description of tuberculous meningitis,<sup>11</sup> and wrote *Observations on the nature, causes and cure of those disorders which are commonly called nervous, hypochondriac, or hysteric* (Edinburgh, 1764). Among other teachers at the Edinburgh Medical School who made notable contributions to knowledge in the mental field were the brilliant Alexander Monro (*secundus*) (1733-1817), who succeeded his father in the Chair of Anatomy in 1758, and described the foramen of Monro and published original observations on the "bursae mucosae" and on the lymphatics; and Sir Charles Bell (1774-1842), whose work on the anatomy of the nervous system is well known, who described Bell's palsy,<sup>12</sup> and held the Chair of Surgery from 1835 until his death in 1842.

Laurence Dopson

### ST. PATRICK'S HOSPITAL, DUBLIN

This Bi-Centenary Record<sup>1</sup> of Swift's "house for fools and mad" gives a factual account of the development of St. Patrick's Hospital, Dublin, from its charter of 1746 and the admission of its first ten patients in 1757, to its present state as a modern psychiatric hospital. The Record was less designed to stand alone than to serve as an annotated catalogue of the exhibition held in the Royal College of Physicians in Ireland, in connexion with the Bi-Centenary and the Dublin meeting of the Royal Medico-Psychological Association, in May 1948. It can therefore hardly be judged as a book; yet it has the more than passing interest which must attach to everything associated with Jonathan Swift, the greatest satirist who has written in English, and Dean of St. Patrick's Cathedral, Dublin, from 1713 until his death in 1745. That his physical tragedy might have been alleviated and the horror of his last years avoided, had he lived in this century, is some indication of medical progress in the last 200 years. His lifelong dread of madness, and his final obliteration in one of its most painful and appalling forms, gains irony in the more modern view of his affliction, here stated in the note by R. Wyse Jackson:

... as Sir William Wilde [father of Oscar Wilde], that remarkable research student of Swift's last days surmised ... Swift's malady was not properly insanity, but a disease of the inner ear. Dr. Bucknill in 1882 suggested that he was suffering from the final cerebral effects of labyrinthine vertigo, a diagnosis which time has not improved on.

The existence of St. Patrick's today, with its modern buildings and treatments, may thus be regarded as, indirectly, a fruit of 18th century medical ignorance.

The "Short Catalogue of the Exhibition" was compiled by M. J. Craig. It shows many interesting items, which include, in addition to Swiftiana, 18th and 19th century books illustrative of the development of medical knowledge of mental disease. From the Royal College of Surgeons of Ireland was lent, for example, a 2nd edition of Pinel's great work, *Traité médico-philosophique sur l'aliénation mentale* (Paris, 1809), together with a copy of the first English translation, *Treatise on insanity* (Sheffield, 1806). Among much valuable material shown by St. Patrick's itself were the 1st folio edition of the famous *Verses on the death of Dr. Swift*, written by himself (London, 1739); two petitions, dated November 1755 and November 1757, from the Governors of the Hospital to Parliament, asking for government grants to supplement the legacy and other moneys which by then had already been spent on building and land; and a copy of Swift's will, together with the Hospital Charters and Bye-laws (Dublin, 1931). Many original manuscript letters and notes, pertaining both to Swift and to the Hospital, were also displayed, and furniture and other objects which belonged to Swift and which form part of the heritage now preserved in St. Patrick's. A clear picture of Swift's *escritoire*, kept in the Hospital board-room, with portraits of Swift, Stella and Vanessa in the background, is reproduced in the present volume, as well as a portrait which is believed to be of Swift. Another illustration shows a portrait of Dr. Robert Emmet, father of the Irish patriot of the same name, and active as governor, physician and business manager of the Hospital from 1770 to 1803.

Sections on "Swift's Heirs" and on "The Buildings" of St. Patrick's Hospital are also contributed by Mr. Craig. Dr. Moore, the Medical Superintendent, in his opening pages on the modern Hospital refers to the enlightened new Mental Treatment Act. Dr. J. D. H. Widdess, Librarian of the Royal College of Surgeons in Ireland, writes a historical outline of the development of St. Patrick's from 1746 to 1899, and also compiles a list of the officers of the Hospital from 1746 to 1948. This list, with its brief notes, repays careful perusal: first of the "Visiting Surgeons" was John Whiteway, son of that Martha Whiteway who was Swift's cousin and bousekeeper and who, as the deafness of his last years gained upon him, "... almost got into a consumption by bawling in my ears." Dr. R. Wyse Jackson writes briefly of "The Vision of Jonathan Swift", referring to the latter's ironic explanations of his own charitable deeds; he quotes both Swift's verses on his own death, and the comment of the *Gentleman's Monthly Intelligencer* on the satiric Dean's bequest of his whole fortune for a hospital for the mad:

The Dean must die! our idiots to maintain!  
Perish ye idiots! and long live the Dean!

During the uncontrollable last attacks of Swift's disease, his attendant beat him to restrain the frenzies into which he was driven by pain and madness. For a long time the Hospital founded by his charity remained chiefly a place of confinement; the report of the Government Commission of 1815 states that St. Patrick's then contained nearly 200 persons, 51 of whom paid for their board and treatment, the rest being maintained by the charity.

There were but six straw patients in the whole establishment, two of whom were quite naked, having torn their clothes to pieces.

Public opinion was roused by the reforms started in 1792 by Pinel in Paris and by the Quakers in England—in 1796 at York, the latter opened The Retreat, an institution for mental patients which is among the best known of mental hospitals today. Gradually amenities and more humane methods were introduced, and in these improvements St. Patrick's seems to have been generally in the vanguard. Yet it was not until 1839 that John Conolly's system of treatment without restraint of the insane was introduced at Hanwell Asylum; by the time his book was published, the "system was being applied to over 10,000 patients in 24 English asylums", according to the catalogue note here accompanying the entry of an example of his book, *The treatment of the insane without mechanical restraints* (London, 1856).

These reforms are not yet complete. Swift's astringencies can be more tonic today than any complacent survey of what has been accomplished since his time; in no country are accommodation, treatment and attendance yet sufficient in either quantity or quality for the needs of the mentally ill. The satirist's legacy, expanded splendidly into St. Patrick's Hospital, two centuries after his death still points one of the great needs in public health.

## MEDICAL AND SCIENTIFIC PHILATELY

One of the most delightful ways of studying the history of medicine or of science is to view it through the eye of the collector. The objects collected are most frequently books and manuscripts, but unwritten history may be read from prints and engravings, or from instruments and drug-jars, and within recent years postage stamps have provided the collector with a new avenue of approach to early medicine and science, a gateway of absorbing interest.

Although medical and scientific philately is little more than ten years old it has attracted considerable attention and has been the subject of more than fifty descriptive articles in the scientific periodicals of eight different countries during those years. But there has been no complete review of the relation between postage stamps and the men and deeds, in medicine and science, which they depict or commemorate. This defect in the literature has now been amply supplied by a librarian and a surgeon, each of whom is an expert philatelist as well as an accredited historian. The result is a fascinating little book<sup>1</sup>. The authors have been concerned with the story behind the stamps, rather than with purely philatelic details. They have been content to stimulate interest in a novel side-line of history, without attempting to enumerate all those stamps which are of medical or scientific interest.

Naturally enough, portrait stamps are the most attractive and also the most numerous in the album of the medico-scientific collector. The first medical man to be portrayed on a postage stamp was Dr. Francisco Espejo, the 'liberator' of his country, who appears upon an Ecuador stamp of 1899, while the first British medical man so to be commemorated was Sir Wilfred Grenfell, whose portrait with the hospital-ship "Strathcona" adorns a Newfoundland stamp of 1941. Other doctors and scientists to whom philatelic honour has been accorded are Imhotep, Vesalius, Paré, Boerhaave, Pasteur, Koch, the Curies, and many others. Conspicuous by their absence are Harvey, Lister, Jenner, and Hunter. Britain has not yet signalized the deeds of her great men by postal commemoration. It may surprise some readers to find among the stamp portraits those of Schiller and Chekhov, of Clemenceau and Sun Yat Sen, until it is recalled that these were medical men who became eminent in other fields. The section dealing with portraiture is made more valuable and interesting by a collection of brief biographies, although the reviewer sought in vain for the Finnish scientist Caloniuss, whose picture is shown on p. 28.

The philately of the Red Cross ranks second only to that of medical and scientific portraits. Indeed, it includes portraits of the founder, Jean Henri Dunant, and of Florence Nightingale, although most of the Red Cross stamps are of symbolic design, as are also many of the stamps issued to assist in the war against tuberculosis, in maternity and child welfare schemes, and in famine relief. A number of stamps are adorned with illustrations of hospitals and sanatoria of universities and medical schools. In this category is included a series of Italian stamps, issued in 1929, and bearing illustrations of the ancient monastery and hospital of Monte Cassino, that noteworthy landmark of medical history which was the scene of violent fighting in the recent war, when the building suffered total destruction. From time to time, medical and scientific congresses have been marked by the issue of special stamps. The latest of such occasions was the Centennial Meeting of the American Medical Association in 1947, when the well-known painting entitled "The Doctor", by Sir Luke Fildes, R.A., which now hangs in the Tate Gallery, was reproduced on a 3 cent stamp.

The reviewer has endeavoured to indicate the scope of a carefully written brochure which, though small, supplies a much-needed account of a new and fascinating bypath of philately and of medico-scientific history. With praiseworthy brevity, the authors have packed into the 24 pages of letterpress a clear and ample outline of the present knowledge, while the illustrations of 148 stamps supply a useful guide to philatelist and historian alike. Print and illustrations are good, although surely such a well-compiled work deserves a better cover, even in times when book-binding difficulties cause many a publisher's headache.

This is a pioneer work, calculated to stimulate interest in medical history as well as interest in postage stamps. There

could be no better present for the schoolboy philatelist or for the adult who takes his hobby more seriously, while even to the reader who tends to scorn the humble postage stamp the book may well serve as an introduction to the history of medicine and science.

## DISSEMINATED SCLEROSIS: AN EARLY ACCOUNT

The severe asthma from which he suffered caused Prince Augustus Frederick, sixth son of George III, to spend much of his early manhood on the continent of Europe. In 1793, while in Rome, he met and clandestinely married the Lady Augusta Murray, being then 20 years old and 11 years younger than his spouse. This marriage was, however, contrary to the provisions of the Royal Marriages Act passed 15 years previously, and was declared invalid, despite a second ceremony at St. George's Church, Hanover Square, London. The two children of the marriage were thus rendered illegitimate.

<sup>1</sup> [For particulars, see Book Reviews, p. 123.]

The boy, Augustus Frederick, was born on 13 January 1794, and his sister Augusta Emma in August 1801. Later in that year the Prince ceased to live with his Lady, who for many years afterwards made strenuous efforts to obtain recognition of her marriage. She was over-indulgent to the boy, both during his schooldays at Harrow and during his life in the Army. He assumed the name Esté in 1809, on the instruction of his father.

Towards the end of 1825, Augustus d'Esté fell in love with the 18-year-old Princess Feodora of Leiningen, half-sister to the young girl who was later to become Queen Victoria. The parents quickly put an end to this affair, and Augustus remained a bachelor for life.

In 1822 d'Esté suffered from a short attack of dimness of vision, which recurred at intervals, accompanied by other symptoms which leave no doubt that he was suffering from what was later recognized as disseminated sclerosis. In his attempts to cope with his affliction he visited many health resorts, both English and European, and was treated by several physicians, but his illness progressed, manifesting all the symptoms associated with disseminated sclerosis, until he died, a pathetic and helpless invalid, in 1848.

The details of the illness of d'Esté would not have become known but for his manuscript diary, in which he recorded in full his symptoms, the prescriptions of his physicians, and other measures taken in a vain effort to cure what was then an unknown malady. The diary itself, *The case of Augustus d'Esté*, came to light, together with a small collection of letters from his mother and others, during a waste-paper drive in 1940. Its historical interest lies in the fact that it is probably the first clinical account of disseminated sclerosis. Sir Robert Carswell first described and depicted a pathological specimen of the conditions in his great atlas, which appeared in parts, being completed in 1838. The illustration was probably completed in 1836, as it is printed by the "lithographers to the King", while later plates in the same atlas were executed by the same lithographers, who now described themselves as "lithographers to the Queen". Jean Cruveilhier was the first to record the history, with pathological correlation, of a case of disseminated sclerosis in 1842, although it is possible that he may have written the history of the case as early as 1838. D'Esté himself was keenly observant and accurate; it is, therefore, not strange that he, a layman, should have compiled so accurate an account of his disease from its first symptoms to its pathetic end.

Chief among the physicians who at one time or another treated d'Esté was Dr. Henry Vaughan, who later changed his name to Halford and eventually became Sir Henry Halford, Bart. He was President of the Royal College of Physicians for 24 years, during which time he was responsible for important changes in the College, including its removal from Warwick Lane to its present site. He also had the unique distinction of being physician-in-ordinary to four sovereigns, George III, George IV, William IV, and Queen Victoria, besides attending many other members of the Royal family.

Credit for the publication of the diary<sup>1</sup>, together with a brief account of the life of Augustus d'Esté, and some of the letters of his mother, is due to Dr. Douglas Firth, who unhappily died before the book appeared. Dr. Firth suggests that the psychological traumata sustained by d'Esté during his unhappy childhood were factors in the etiology of his disease. This little book is a most valuable and interesting contribution to the history of medicine.

<sup>1</sup> [For particulars see Book Reviews, p. 123.]

Dr. Jonckheere.<sup>1</sup> This papyrus is small in comparison with other well-known medical papyri, consisting merely of eight columns, and is entirely devoted to affections of the anus. It is divided into small paragraphs, each with a heading in red ink and consisting of prescriptions for various anal maladies written in almost modern style with a list of constituents, and directions for their compounding and employment. The absence of any reference to magic is notable. Constituents include chiefly vegetable products, such as honey, dates, raisins, and oils, various salts, and human and goats' milk. The compounds are in some cases for oral medication and in others for use as suppositories, enemata or local application to the anus. Indications for their employment are not always clear, but there are references to such conditions as anal prolapse and haemorrhoids.

### AN ENCYCLOPAEDIA OF MEDICAL SOURCES AND EPONYMS

This is the most exhaustive source-book<sup>1</sup> of eponyms so far available. The idea of publishing lists of medical eponyms and references to important original work is of course not new. The late Dr. Isidor Fischer's *Eigennamen in der Krankheitsterminologie*, which appeared in 1931, has proved its worth, and the *Medical bibliography* of Garrison & Morton (1943) includes annotated references both to original papers and to important eponyms, while Dr. Kelly himself has already earned the thanks of medical historians by his scholarly editorship of five volumes of *Medical classics*, in which he made available reprints of the original texts (and translations where necessary) of classical papers in medicine, together with full bibliographies of the writers and the eponyms associated with them.

In this new book he has brought together in alphabetical order over 5,000 personal names with the eponyms connected with them, and gives full title and reference, with dates and brief descriptions of the persons concerned. Important original papers are also included. The references are extremely accurate, but unfortunately the text itself suffers from bad proof-correcting. Misspellings such as "anomaly", "syphygmonograph", "Frölich", "Frählich", should not have been overlooked. Few will recognize Sir Arthur Hurst under his original name of Hertz. On page 326 there is an entry for "Pinto's disease", which is said to be described by E. del Pinto, although pinto (pinta, carate) is generally considered to have been so named from the Spanish *pintar*, to paint. Some of the descriptions of the writers will not be universally acceptable; Sir William Osler is described as a "Canadian, American and English physician"; Lettsom, founder of the Medical Society of London, as a "Virgin Island physician"; Sir Thomas Lewis, the Welshman who achieved his great reputation as a cardiologist in London, as an "English physician"; the Italian Aldo Castellani as an "Anglo-Indian physician"; and Sir Howard Florey, the Australian professor of pathology at Oxford, as an "Oxford pathologist". Henry Newell Martin, the Irish physiologist who was a Fellow of the Royal Society and became professor of biology at Johns Hopkins, is described as "a Baltimore biologist". Many emigrants are described as belonging to the land of their adoption, particularly when this is the USA, even when the work ascribed to them was written in their native land. An immense amount of labour must have gone into the preparation of this book, but insufficient care seems to have been taken in the final stages.

These shortcomings, however, do not prevent the book from deserving its place as one of the most important additions to medical bibliography of recent years, of value alike to medical students, practitioners, research workers, librarians, and medical historians. The writer is to be congratulated on his great industry in producing it.

## ANAESTHESIA

### 1331 The Chemistry of Anaesthesia

John Adriani. Oxford: Blackwell Scientific Publications, 1946. viii + 530 pages; 45 figures. 23 x 15 cm. £1 15s. [£1.75]

Part I. The physical behaviour of gases; (i) The physical behaviour of gases; (ii) the chemistry of absorption of carbon dioxide in rebreathing; (iii) the chemistry of anaesthesia. (v) The chemical nature of anaesthetic drugs; (vi) hydrocarbons; (vii) alcohols; (viii) aldehydes and ketones; (ix) acids, acyl derivatives, and esters; (x) ethers, alkene oxides, and acetals; (xi) halogenated compounds; (xii) sulphur-containing substances—sulphonemethanes; (xiii) aromatic and heterocyclic compounds; (xiv) opium and opium alkaloids; (xv) amides, ureides, and related compounds; (xvi) local anaesthetic drugs; (xvii) drugs affecting the autonomic nervous system; (xviii) stimulating drugs used as anaesthetics; (xix) standards of purity of drugs; (xx) inflammability of anaesthetic mixtures. Part III. Biochemistry related to anaesthesia. (xxi) Chemical basis of proposed mechanisms of narcosis; (xxii) effects of anaesthesia upon composition of body fluids; (xxiii) effects of anaesthesia upon composition of body fluids (continued); (xxiv) effects of anaesthesia upon composition of body fluids (concluded); (xxv) the effects of anaesthesia on liver function; (xxvi) effects of anaesthesia upon formation and composition of urine; (xxvii) effects of anaesthetic drugs on lipid and nervous tissues; (xxviii) enzymes, vitamins and hormones; (xxix) metabolism during anaesthesia; (xxx) detoxification and elimination of anaesthetic drugs; (xxxi) toxicology; (xxxii) biochemical aspects of local anaesthesia. Bibliography. Glossary. Appendix. Index.

Anaesthesia has become such a highly technical subject in recent years that there is a real danger that the basic sciences upon which it is founded will be forgotten.

The part which physics plays in the specialty has already been dealt with by an admirable textbook from Oxford. Professor Adriani now sets out with a similar object on behalf of chemistry and he has succeeded very well.

The book is divided into three sections—inorganic chemistry, organic chemistry and biochemistry. These are followed by a most comprehensive bibliography of 44 pages, a glossary of technical terms, various tables of reference, and an index.

The style is clear and lucid and every variety of general anaesthetic, basal narcotic and local analgesic is dealt with from the chemical aspect. The only statements found which do not entirely correspond with opinion in Great Britain concern synergism and trichlorethanol. The existence of the former phenomenon is not universally admitted by pharmacologists; and no mention is made of the risk of primary cardiac failure which led to the abandonment of trichlorethanol in this country.

The book is excellently produced and has very few printing errors.

C. Langton Hewer

### 1332 The Development of Inhalation Anaesthesia: with Special Reference to the Years 1846-1900

Barbara M. Duncum. London: Geoffrey Cumberlege, Oxford University Press, 1947. (Publication of the Wellcome Historical Medical Museum.) xvi + 640 pages; 161 figures. 22 x 14 cm. £1 15s. [£1.75]

Part I. The preparatory period. (i) Respiration and pneumatics; (ii) etherization. Part II. The use of ether. (i) physiology of anaesthesia; (ii) with chloroform. Part III. The period of the predominant use of chloroform. (vii) Search for the 'perfect' anaesthetic; (viii) chloroform in practice c. 1850-70; (ix) the Chloroform Committee of 1864. Part IV. Revived use of nitrous oxide and of ether. (x) Nitrous oxide; (xi) ether in England. Part V. Continental developments. (xii) Paul Bert's contribution; (xiii) 'mixed anaesthesia' and premedication; (xiv) ether on trial: Switzerland—Denmark—Germany—France. Part VI. The beginning of modern anaesthesia. (xv) Hyderabad Commission and its consequences; (xvi) anaesthetic trends in England, 1890-1900; (xvii) some new developments; (xviii) the jubilee of anaesthesia. Appendices. Summary of events in anaesthesia, 1772-1911. Index.

It is appropriate that Oxford should produce this volume, which is as outstanding for its literary qualities as for its precise and ever interesting presentation of the details of the discovery and subsequent development of inhalation anaesthesia. A notable feature of the book is the documentation, which is ample

but never redundant or irrelevant. Dovetailing of quoted excerpts into the text is accomplished with an adroitness that preserves the continuity of the narrative. In dealing with bygone controversies, of which this particular subject has had an unenviable share, the author shows considerable forensic ability and discrimination in assessing the evidence, an excellent example of this being her co-ordinated analyses and discussion of the reports of the Glasgow (1880), Hyderabad (1889) and later Committees which considered the then serious problem of deaths under chloroform. The many colourful personalities who played parts in this significant epoch of medical history must have been tempting subjects for biographical digression, but although, probably wisely, this has been kept minimal, the reader is given adequate delineation of the characters themselves by the abstracts from their writings. Illustrations of high quality, a clear format and typographical excellence are production features worthy of the authoritative text.

The book will appeal to general readers as much as to specialists, but for the latter the historical interest is supplemented by informative technical and physiological data, associated with the evolution of inhalational methods, which they would do well to ponder.

John Gillies

## AVIATION MEDICINE

### 1333 Pilot Error: Some Laboratory Experiments

D. Russell Davis. London: His Majesty's Stationery Office, 1948. (Air Ministry, A.P. 3139A.) 39 pages; 9 figures. 24 x 15 cm. 9d. [£0.0375]

(i) The role of laboratory experiment in the study of pilot error; (ii) principal results; (iii) analysis of the errors; (iv) individual differences of reaction; (v) applications to flying. Index.

The author of this monograph has made a valiant attempt to assess those characteristics which render pilots liable to accidents in handling the complicated pieces of machinery embodied in modern warplanes. During the war, he investigated a large number of pilots on a tripartite basis. Firstly, he employed a device known as the Cambridge Cockpit, designed by the late Dr. K. J. W. Craik, which sought to reproduce, on terra firma, actual flying by instruments. A second test, the Skilled Response, explored reactions to simple, complicated and ambiguous stimuli. Finally, Dr. Davis scrutinized the psychiatric assessments of pilots as regards neurotic predisposition, with a view to correlating these findings with his cockpit experiments. He elicited three major types of reaction to his cockpit: (i) overactivity with tension and occasional florid anxiety; (ii) inertia with flagging interest and mild boredom; and (iii) certain end effects associated with the approaching termination of the test, consisting largely of relaxation of effort.

*Inter alia*, ancillary experiments revealed that noise had variable, highly individual and unpredictable effects and that drugs were of no special importance except, as usual, in the case of alcohol. Doses of whisky (a good brand of Scotch whisky is specifically mentioned!) produced severe performance deterioration, confirming what is already known of the effects of alcohol on skilled occupations. Furthermore, special instructions, which warned pilots of the kinds of possible error and other adverse circumstances, had a favourable effect which became less evident the later in the test these were imparted. Fatigue was found to play little or no part in the causation of pilot error. Rather was it anticipatory tension which interfered with performance.

In this regard, psychiatric assessments and subsequent "follow-ups" proved interesting. Over 1,000 pilots, including 39 neuro-psychiatric patients, were interviewed, 383 having been submitted to the Cockpit Test. They were classified in respect of neurotic predisposition and again as to whether their reactions were normal, overactive or inert. Briefly, the patients revealed a very high percentage of abnormal reactions. Those with anxiety states tended to over-react whereas hysterics revealed inertia; the more severe the neurotic predisposition the larger the proportion of abnormalities.

As regards prognostic indications a follow-up showed that "inert reactors" were much more frequently suspended from flying training than other subjects, sustained more fatal accidents

## A SURVEY OF THE FIRST YEAR'S WORKING OF THE NATIONAL HEALTH SERVICE IN GREAT BRITAIN

This extra number presents an impartial review of the first year of the National Health Service. Great care has been taken to select contributors who are outstanding in their own spheres, who have an intimate knowledge of the working of the Act and, above all, men free so far as possible from prejudice and representing no party or sectional interests. The extra number may be purchased individually (price 5s), or included without additional cost with all new subscriptions. New subscriptions may be started with the October issue, a Special Number on Advances in Treatment, 1949, an international review of the progress of medicine during the past year.

### SOME PRESS OPINIONS

- 'A valuable review . . . gives facts and, to a lesser extent, opinions on what has been happening since July 1948, in hospitals, in general practice, in the local health authorities' services, and in the central administration.'—*The Times*.
- 'The many Americans who want to know how the health service is working in practice can hardly do better than to buy a copy of the special number of *The Practitioner* which is devoted entirely to the subject. Articles have been contributed by practitioners in every major branch of the service.'—*The Economist*.
- 'Though the National Health Service completed its first year nearly three months ago no serious examination, official or unofficial, had been made till *The Practitioner* undertook such a comprehensive survey.'—*The Spectator*.
- '*The Practitioner* is always readable, reliable and practical. In its review of the first year's working of the National Health Service it maintains its reputation for fair play by presenting a series of articles untingered by political opinion.'—*Time and Tide*.
- 'It should be useful both to present inquirers and to future historians to have *The Practitioner's* review of the National Health Service's first year . . . Altogether *The Practitioner* is to be congratulated on producing a readable and illuminating symposium.'—*The Lancet*.

110 pages of text. Price 5s.

*The Practitioner* circulates to doctors in general and specialist practice all over the world. The contents are essentially practical; each number contains a symposium on a subject of topical importance, thus presenting the reader with a continuous postgraduate refresher course.

### RECENT AND FORTHCOMING NUMBERS

ADVANCES IN TREATMENT, 1949. A Special Number, published October 1. 136 pages of text. Price 7s. 6d. (free to subscribers).

ENDOCRINOLOGY. A symposium—November 1949.

RESPIRATORY DISEASES. A symposium—December 1949.

The annual subscription is £2 2s. post free. Orders can be placed through the principal booksellers or agents, or the form below can be used. Distributed in U.S.A. and Canada by The International Practitioner Company, 12 East 41st Street, New York City, at \$8.50 post paid.

## Modern Discoveries in Medical Psychology

CLIFFORD ALLEN M.D.

The story of the discovery of the unconscious mind is the subject of this remarkable book, the second edition of which has just been published. The author is Physician in charge of the Psychiatric Department of the Seamen's Hospital, Greenwich, and Psychiatrist to the Ministry of Pensions. The contents consist of chapters on Mesmer and the Discovery of Hypnosis, Janet and the Structure of Consciousness, Morton Prince and Multiple Personality, Freud and the Discovery of Psychoanalysis, The Further Discoveries of the Psychoanalysts Adler and the Power Instinct, Jung and the Hinterlands of the Mind, Kretschmer and the Relation of Body and Mind, Pavlov and the Machinery of the Mind, Wagner-Jaureg and his Followers.

Second Edition, revised and enlarged. 12s. 6d. net

**Macmillan & Co., Ltd.**

and more often became operational casualties. In the final analysis, this paper demonstrates conclusively the importance of temperamental factors in determining the safety of potential pilots. It follows that tests of temperament predicting *panache* or the reverse in pilots are eminently necessary. However, it is doubtful whether the Cockpit Test satisfies the requirements. It is free from aerial hazards and can be applied only to individuals with flying experience. Furthermore, psychiatric scrutiny as an adjunct is not infallible; there are too many imponderables in the totality of neurotic predisposition.

Nevertheless, the author has made a distinctive and valuable contribution to a difficult topic and his declaration that much more research is necessary in this field can be fervently endorsed.

H. C. Beccle

### 1334 Aviation Medicine in its Preventive Aspects. An Historical Survey

John F. Fulton. London: Geoffrey Cumberlege, Oxford University Press, 1948. (University of London Heath Clark Lectures, 1947.) viii + 174 pages; 43 figures. 22 x 14 cm. 12s. 6d. [£0.625]

(i) Altitude sickness and acclimatization: the history of oxygen; (ii) decompression sickness: the genesis of the tissue bubble; (iii) pressure cabins and explosive decompression: the spring of the air; (iv) effects of acceleration: dim-out and black-out; protective measures; (v) man and the machine: problems of safety in flight. Index.

This is an interesting historical survey of certain important researches and developments in aviation medicine carried out by the Allies during the war period 1939-46. It is divided into five chapters, dealing respectively with altitude sickness and acclimatization, decompression sickness, the physiological problems of pressurized aircraft cabins, the effects of acceleration on man, and the problems of safety in flight.

The recent altitude acclimatization experiment carried out at the United States Naval Air Station in Pensacola, Florida, is described in some detail. This interesting investigation, named "Operation Everest", was under the direction of Commander Charles Houston, who had twice climbed in the Himalayas. The experiment was devised to secure impartial data on the respiratory and circulatory changes which occur through acclimatization to lack of oxygen at an altitude level of 23,000 feet without supplementary oxygen. Four young adults lived for five weeks in a low-pressure chamber fitted with an air lock, so that observers could enter to make observations and take appropriate samples. The results showed that acclimatization consists of a series of integrated adaptations to restore the oxygen pressure of the tissues to the normal sea-level value.

Decompression sickness is reviewed, from Leonard Hill's work in 1912 on the caisson sickness of divers, resulting from too rapid an ascent from depths and causing acute body pains ("bends") and respiratory distress ("chokes"), to similar conditions which occurred among personnel in the RAF in 1939 engaged in high-altitude photographic reconnaissance. Researches by the RAF Physiology Research Team at Farnborough, followed by those of the Canadians and Americans, are dealt with in some detail, particularly the fundamental research under the chairmanship of Dr. John Fulton. The American group studied bubble formation in the blood and tissues of animals in relation to "bends", and the underlying factors, such as gas tension, hydrostatic pressure, surface tension and gas nuclei. These researches led to practical results in operational flying, whereby "bends" were prevented or ameliorated by pre-oxygenation before a high-altitude flight, and by limitation of muscular movements during flight to lessen the formation of bubbles in the blood vessels.

As regards pressurized aircraft cabins, the valuable data obtained by Piccard of Belgium and Stevens and Anderson of the USA, using pressurized gondolas, were instrumental in enabling Harry Armstrong at Wright Field to draw up in 1935 the first specification of physiological design criteria for such cabins (published in abstract form in 1936). The main physiological problems concerned ventilation and explosive decompression. The first work on explosive decompression was done by the French workers, Garsaux, Richou and Laurent, in 1939, using animals. In 1941, R. H. Winfield in Great Britain and J. J. Smith in the USA, independently experimenting on themselves, showed that no perceptible harm is caused to a fit man by explosive decompression, provided an adequate supply of oxygen

is immediately available, or a rapid descent is made to non-oxygen-requiring altitudes. Survival times after explosive decompression at various altitudes up to 75,000 feet were worked out by Gelfan, Nims and Livingston in the USA. At altitudes above 52,500 feet, respiration ceases within 18 seconds after such an explosion. The time of "useful consciousness" without oxygen at 30,000 feet was found to be approximately 2 minutes, and if oxygen were not supplied, death would occur within 10 minutes.

Broca and Garsaux in France in 1918 were the first to demonstrate the pathological effects on animals of high centrifugal acceleration. The Germans initiated centrifugal researches on man in 1935. In Great Britain intensive researches of an *ad hoc* nature were begun in 1939 by Matthews and Stewart, using a flying laboratory in an aircraft fitted with a cine-camera to record the effects of high acceleration under conditions of aerial combat. This enabled suitable remedies to be devised. Important fundamental researches in centrifugal machines in the laboratory, first in Canada by Franks, then in Australia by Cotton, and later in the USA at the Mayo Clinic, Wright Field, and Pensacola, added much to our knowledge of the effects of centrifugal forces on man, and culminated in the development of anti-gravity suits, first of the hydraulic type and later of the air-pressure variety. It is claimed that the air-pressure anti-gravity suit did much to give Allied fighter pilots ascendancy over the enemy.

The problems of safety in flight include valuable work by De Haven in the USA from the study of the effects of forces of deceleration on man as demonstrated in aircraft crashes and non-fatal suicidal leaps. The protective value of seat-belts, safety harness, stressing of seats, backward facing seats, and "ditching drill", as adopted by the RAF, is reviewed.

## BRITISH PHARMACOPOEIA

### 1335 British Pharmacopoeia 1948

General Council of Medical Education and Registration of the United Kingdom. London: Published for the General Medical Council by Constable & Co. Ltd., 1948. xi + 914 pages. 23 x 15 cm. £2 5s. [£2.25]

(i) General notices; (ii) precautionary legal notice; (iii) monographs. Appendices. Index.

[The appearance of this edition, the 7th, of the *British Pharmacopoeia* is an event of considerable interest and importance. The 6th edition was published in September 1932; war conditions made it impossible to bring out the following edition at the normal 10-year interval. The present volume, therefore, bridges a gap of some 17 years. Seven addenda to the 6th edition have appeared; in the present volume these have been largely revised prior to inclusion. This work is a continuing enterprise, and much of the labour for the present volume was therefore carried out under war conditions with their attendant difficulties. The acceleration of medical research due to the demands of war has further added to the labours of the authors. A review by Professor Mayrs of the new edition appears below.]

Since the *British Pharmacopoeia* (B.P.) was first compiled in 1864 one of its purposes seems to have undergone a gradual change. A drug was not necessarily excluded from the early issues after its therapeutic value had become doubtful. The *Pharmacopoeia* thus maintained standards for drugs in common use, without much regard for their actual usefulness. As stated in the preface to the issue of 1867, the object was "not so much the selection as the definition of substances which the physician requires." But in 1932 evidence of a different attitude began to appear. Some valueless drugs, still widely employed, were excluded; so that pressure, however slight, was directed against their use. In the new issue this attitude is more obvious; none of the drugs included can be described as useless, though a few may be considered unnecessary.

While the disappearance of a drug from the *Pharmacopoeia* usually indicates that it has failed to hold its place in therapeutics, the absence of a new drug does not imply that it is without merit. An interval must elapse before its therapeutic and toxic effects are confirmed, and for this and other reasons judgement must be postponed. The 1948 B.P. appears to contain most of the new drugs about which there is now fairly general agreement.

In the preface to the new *Pharmacopoeia* the General Medical Council states that its preparation has been more laborious than that of any of its predecessors. This can well be believed, and the Pharmacopoeia Commission is to be congratulated on a fine piece of work. The compilers do not claim the divine inspiration of Aesculapius to protect them from criticism, but they are protected to some extent in another way. They have had at their disposal the views of experts in many branches of medical science, while few potential critics are likely to be expert in more than one.

Some points of interest to medical men may be mentioned. The pure glycoside ouabain, which appeared under the name strophanthin-G in the 7th Addendum to the 1932 issue, has replaced strophanthin (the mixture of glycosides from *Strophanthus Kombé* Oliver). Its official recognition has been slow, and it may suffer in competition with the newer drug, digoxin, which has had a shorter period of probation. The maximum dose recommended for ouabain is one-fourth that of the old strophanthin.

The synthetic anthelmintic, diphenan, known for many years under various proprietary names, has now become official—perhaps an admission that gentian violet does not completely solve the problem of treating threadworm infestation. Diphenan is a relatively non-toxic substance.

An unusual event is the reappearance of a drug which once lost its official status. Picrotoxin was included in the 1898 B.P. but was rejected in 1914. Its value in the treatment of narcotic (especially barbiturate) poisoning is now recognized. The retention of squill and the continued recommendation of oral doses for the double salts of antimony may cause some surprise. Squill, though much used, has disadvantages as an expectorant, and would probably not be missed; tartar emetic is seldom given by mouth.

Crude preparations of cinchona have disappeared, and the minimum dose recommended for the chief quinine salts has been increased. The use of quinine as a bitter tonic is thus discouraged.

Doses in general have not been much altered, and the few changes which have been made seem to conform with current practice. The doses of some vitamins have been increased, the dosage of dilute hydrochloric acid has been doubled, and the maximum dose of chloral hydrate has been raised to 30 grains. The dosage of quinine sulphate is halved. Small metric doses of solids are now expressed in milligrams instead of grams.

The numerous injections and tablets now included are probably of more direct interest to manufacturers than to doctors; but, before prescriptions are written, the availability of tablets of the required drug-content should be ascertained.

A leaflet has been issued with the *Pharmacopoeia* in which are listed the official names of recent pharmacopoeial drugs, and also approved names for some other drugs not at present included. If the nomenclature of drugs is to be saved from hopeless confusion these names must be used whenever possible.

This new B.P. is in no danger of unfavourable comparison with its predecessors.

E. B. C. Mayrs

## CARDIOVASCULAR SYSTEM

### 1336 Electrocardiography and Clinical Disorders of the Heart Beat. A Handbook for Practitioners and Students

Thomas Lewis. London: Shaw & Sons Ltd., 1949. xiv + 285 pages; 215 figures. 22 × 14 cm. £1 5s. [£1.25]

(i) The electrocardiographic method; (ii) the physiological electrocardiogram; (iii) the electrical axis; (iv) rhythmic but anomalous electrocardiograms; (v) electrocardiogram of special states; (vi) sinus slowing and irregularities; (vii) heart-block; (viii) premature contractions or extrasystoles; (ix) simple tachycardia; (x) paroxysmal tachycardia; (xi) auricular flutter; (xii) auricular fibrillation; (xiii) ventricular fibrillation and premonitory mechanism syncope; (xiv) competing rhythms; and some rare disorders; (xv) alternations of pulse and heart. Appendix. Index.

In this last publication of the late Sir Thomas Lewis two of his previous works, *Clinical disorders of the heart beat* and *Clinical electrocardiography*, are presented in one volume with obvious advantages. The book is written for practitioners and students, and although the author claims to have brought its contents up to date, it is better regarded as a classic than as a modern

treatise; as such it must occupy a welcome place in our library. At the same time, it reminds us sharply that the host of new leads has extended the practical value of electrocardiography but little, and has added nothing to the analysis and interpretation of disorders of rhythm; thus this latter section reads as well today as when it was first written.

Not the least of Lewis's many great qualities was his ability to describe in simple terms the conclusions to which he had been led by much hard work and complex experiment, so that the general practitioner and ordinary patient could benefit directly from them. It is indeed a pleasure to turn from the jargon of current medical literature to the well-constructed phrases and precise English of a scientist who knew how to write.

Paul Wood

### 1337 Subacute Bacterial Endocarditis

Emanuel Libman & Charles K. Friedberg. Second edition. New York: Oxford University Press, 1948. vii + 113 + 3 pages; 19 figures. [Reprinted from Oxford Loose-Leaf Medicine with the same page numbers as in that work.] 24 × 16 cm. £1 1s. [£1.05]

(i) Definition and classification of endocarditis; (ii) classification of bacterial endocarditis; (iii) subacute bacterial endocarditis; (iv) mild cases of subacute bacterial endocarditis; (v) the bacteria-free stage; (vi) transitional cases of subacute bacterial endocarditis; (vii) recurrent cases of subacute streptococcal endocarditis; (viii) prognosis of subacute bacterial endocarditis; (ix) cause of death in subacute bacterial endocarditis; (x) prophylaxis of subacute bacterial endocarditis; (xi) treatment of subacute bacterial endocarditis. Bibliography.

The well-known contributions of the late Dr. Emanuel Libman to the study of subacute bacterial endocarditis have been revised by Dr. Charles Friedberg. This monograph provides an exhaustive study of the pathology, symptomatology and treatment of this fascinating and important disease. The bibliography is complete and includes the experience with penicillin and other forms of chemotherapy up to September 1947.

With the change in outlook of the disease and modification of its course by modern treatment, a good deal of new basic knowledge is bound to accrue. Opportunities will arise for direct microscopic study of the mode of healing of bacterial endocarditis, and the long-term results of some of the renal complications in cases where the primary cardiac condition has been cured will require further study. The purpose of the Oxford Loose-Leaf Medicine is to keep the readily available information well up to date, and this monograph can be thoroughly recommended to all who are interested in the immense variety of clinical manifestations arising in the course of subacute bacterial endocarditis.

## CHEMOTHERAPY

### 1338 The Basis of Chemotherapy

Thomas S. Work & Elizabeth Work. Edinburgh: Oliver & Boyd Ltd., 1948. xx + 435 pages; 42 figures; 38 tables. 23 × 15 cm. £1 6s. [£1.3]

(i) Introduction: historical; (ii) cell metabolism; (iii) essential metabolites; (iv) enzyme inhibition; (v) drug antagonism; (vi) drug resistance; (vii) the relation of structure and activity of drugs. Epilogue—Chemotherapy as a science. Index.

A broad account of the theoretical principles on which modern chemotherapy is based has long been needed. Though limited advances can be made by the extension of facts based on empirical discoveries, true progress in a subject must rest on a sound knowledge of its underlying principles. Of all the branches of medical science, chemotherapy provides perhaps the best example of a field of enquiry which is the meeting-place of many different sciences. To give a logical account of its development and of its future possibilities, it is necessary therefore to extract the relevant principles from these sciences, and to show the synthesis from them of the new knowledge of the mode of action of antibacterial substances.

With this in view the authors of this book have wisely included chapters of a more general nature on cell metabolism and on the mechanism of enzyme inhibition. They have described the main enzyme-catalyzed reactions on which the life of the cell depends, and have summarized the evidence on which is based the view that

a given metabolite is essential for a given bacterial species because it is a constituent of one of these essential enzyme systems, which the bacterial cell cannot itself synthesize. Seen in the light of this work, it now seems probable that substances act as growth inhibitors because in one way or another they inhibit these enzyme systems, and a clear account is given of the relation of bacterial growth inhibitors to essential metabolites, and of the various ways in which enzyme inhibition may be brought about.

Recent developments which are beginning to throw light on the relation between chemical structure and chemotherapeutic activity are also described, and the way is indicated for future developments in this field.

A welcome inclusion in this book is a well-written chapter on the history of the development of modern chemotherapy, an introduction that traces the subject back past Koch and Lister and Pasteur to the earlier proponents of the theory of the contagious nature of disease. It is a book which presents in a clearly written way the development and the logic of modern chemotherapy; while paying due attention to the broad principles underlying the subject, it presents a complete and up-to-date picture of our present knowledge of its mechanisms, and, with its full bibliography, is therefore of value and of interest to the research worker as well as to the advanced student.

R. H. S. Thompson

## CHEST DISEASES

### 1339 A Practical Manual of Diseases of the Chest

Maurice Davidson. Third edition. London: Geoffrey Cumberlege, Oxford University Press, 1948. xvi + 670 pages; 268 illustrations. 25 x 17 cm. £2 10s. [£2.5]

Section A. Preliminary considerations. (i) The elementary anatomy and physiology of the respiratory mechanism; (ii) radiology of the chest; (iii) the relation of chest disease to general medicine and pathology; (iv) systematic examination in disease of the chest. Section B. Diseases of the upper respiratory tract. (v) Diseases of the nasopharynx; (vi) diseases of the larynx. Section C. Diseases of the lower respiratory tract. (vii) Bronchitis; (viii) bronchiectasis; (ix) foreign bodies in the bronchi. Section D. Asthma. (x) Asthma: aetiology and pathology; (xi) asthma: clinical features and treatment. Section E. Diseases of the pleura. (xii) Pleurisy and pleural effusion; (xiii) pneumothorax, etc.; new growths of pleura. Section F. Diseases of the lungs. (xiv) Conditions affecting the air in the alveoli; (xv) conditions affecting the circulation in the lungs; (xvi) the pneumonias; (xvii) the pneumonias (continued); (xviii) fibrosis of the lung; (xix) industrial respiratory diseases; (xx-xxiv) pulmonary tuberculosis; (xxv) specific non-tuberculous infections of the lung. Section G. Intrathoracic suppuration. (xxvi) General principles in the diagnosis and treatment of intrathoracic suppuration; (xxvii) empyema thoracis; (xxviii) abscess and gangrene of the lung. Section H. Intrathoracic new growths. (xxix) Malignant new growths of the lung and bronchus; (xxx) non-malignant growths of the chest; (xxxi) prognosis and treatment in bronchial carcinoma; (xxxii) lymphadenoma; (xxxiii) cysts of the lung and pleura. Miscellaneous. (xxxiv) Differential diagnosis in regard to certain obscure clinical and radiological phenomena; (xxxv) affections of the mediastinum; (xxxvi) sarcoidosis; (xxxvii) oxygen therapy. Appendix. Formulae of prescriptions. Index of authors. Index of subjects.

Dr. Davidson's textbook of diseases of the chest was first published in 1935. The appearance of the 3rd edition has been delayed by the war. In it he has made a number of additions and revisions. Certain of the reproductions of radiographs have been replaced by more satisfactory ones. The basic plan of the book, however, remains unchanged. Its object is to present from the point of view of the practical physician a readable account of current practice in chest diseases. Case reports from the author's life-long experience are added in the text to illustrate practical points. At the end of each chapter there is an adequate list of references both to more detailed textbooks on special subjects and to original papers.

Dr. Davidson's literary style is leisurely, and brings with it a reminder of more spacious days. The younger physician will find described here certain methods which he may think outmoded; for instance the creosote chamber in bronchiectasis, and the use of atropine for pulmonary oedema. While the emphasis of the book is on practical aspects, space is not always allocated in accordance with the importance and frequency of diseases in practice; for instance the section on asthma consists of only 19 pages out of the 670 which the book contains. It is unfortunate that in the chapter on bronchiectasis the diagrams and nomenclature of bronchial anatomy published by Nelson in 1934 are reproduced; whereas in a note on the anatomy of the bronchial

tree and in the section on bronchography, which has been revised, with very helpful line drawings to clarify the illustrative bronchograms, the later anatomical nomenclature of Foster-Carter and Hoyle is used. Certain omissions are an indication of the rapid advances which have been made in knowledge in the last few years. For instance the clinical application of streptomycin has developed so recently that it is not mentioned in the section on pulmonary tuberculosis; in the section on fungus diseases of the lung coccidioidomycosis and histoplasmosis, on which so much recent work has been done in the USA, receive no mention; and in the section on atypical pneumonias rickettsial and ornithotic pneumonias are not mentioned.

These are minor criticisms; on the whole the book can be recommended as a reliable account of chest disease, which will rarely fail to give the physician some indication of what to do when faced with practical clinical problems, and will give the student an acquaintance with chest disease soundly based on clinical experience.

J. G. Scadding

### 1340 The Child's Lung: Developmental Anatomy, Physiology and Pathology

Stefan Engel. London: Edward Arnold & Co., 1947. viii + 332 pages; 283 illustrations. 22 x 14 cm. £2

Part I. The bronchial tree and the bronchial glands. (i) Macroscopical anatomy; (ii) the bronchial and bronchiolar distribution and arrangement; (iii) the developmental histology of the bronchial tree; (iv) the patency of the air-passages; (v) the air-cleansing function of the bronchial tree; (vi) general pathology of the bronchial tree; (vii) bronchial and bronchiolar catarrh, bronchitis and bronchiolitis; (viii) bronchiectasis; (ix) the bronchial glands; (x) the hilum; (xi) pathology of the bronchial glands. Part II. The lung. (xii) The foetal lung; (xiii) developmental anatomy of the thorax and the lung; (xiv) general remarks on the histology of the lung; (xv) the respiratory bronchioles; (xvi) the acinus of the infant's lung; (xvii) the growth of the lung; (xviii) the elements of the lung-tissue; (xix) the blood supply of the lung-tissue; (xx) the alveolar pores; (xxi) function of lung in relation to morphology; (xxii) unifocal or lobar pneumonia; (xxiii) dyslectatic-paravertebral pneumonia; (xxiv) multifocal or broncho-pneumonia; (xxv) radiology; (xxvi) the miliary tubercle; (xxvii) the pulmonary primary tuberculous complex in various age-periods; (xxviii) diseases of the lung according to age-periods. References. Index.

This book describes the anatomy, physiology and pathology of the child's lung, and is based on original work done by the author at the Hospital for Sick Children, Great Ormond Street, London, where he was a special research fellow.

It is divided into two parts: Part I deals with the bronchial tree and bronchial glands and Part II with the lung itself. In the earlier chapters, the author points out the relative lengths in the bronchial tree of the trachea and main bronchi at various ages, from the newborn infant to the adult. Three facts emerge: (i) the trachea and main bronchi do not grow continuously at the same rate; (ii) the right bronchus is wider than the left, and (iii) the ratio of the right to the left bronchus remains unchanged from birth to adult life. The author also points out the comparatively short length of the trachea during the early years of life and attributes to this fact, among other considerations, the greater prevalence of catarrhal bronchial disease in young children.

Several chapters are devoted to the exact anatomy of the bronchi and bronchioles and its bearing on the pathology of bronchitis, bronchiolitis, bronchiectasis, collapse, etc. In addition, an exact description is given of the bronchial glands and their relation to primary foci and to tuberculous meningitis. In this connexion, the author points out that, as a result of much investigation, it has been found that cases of low-grade pyrexia and general ill-health hitherto attributed to hilar tuberculosis may occur with equal frequency in children who are Mantoux negative. The statistics which he gives of hilar tuberculosis in various age-groups are of considerable interest. He groups forms of pneumonia under six headings: (i) dyslectatic, paravertebral pneumonia (infants); (ii) septic pneumonia (infants); (iii) foreign body (aspiration) pneumonia, lipoid pneumonia; (iv) multifocal pneumonia (bronchopneumonia); (v) unifocal (lobar) pneumonia; (vi) "atypical pneumonia" (pulmonary inflammation, pneumonitis). A full description of each variety and their relative occurrences at different ages is given.

It is worth noting that, in a series of 313 cases of measles, there were 86 cases of pneumonia and among them 55 (64%) were of multifocal, and 31 (36%) of unifocal, character. The mortality in the first category amounted to about 55%, whereas in the second group no deaths occurred.

The chapter on radiology and its relation to anatomy and pathology is of some importance. There is also a short chapter on military tuberculosis, pointing out that, in addition to the better-known malignant type, there is a benign type from which recovery is usual. A special chapter of great interest is devoted to diseases of the lungs according to age-groups. At the end of the book is an extensive and useful list of references to books, monographs and papers bearing on the subject.

A. G. L. Reade

## CHILD PSYCHIATRY

### 1341 *The Psychoanalytic Study of the Child.* Volume II 1946

Edited by Anna Freud et al. London: Imago Publishing Co., Ltd., 1947. 424 pages. 24 x 16 cm. £1 10s. [£1.5]

(i) Problems of child development; (ii) clinical problems; (iii) guidance work; (iv) problems of education and sociology; (v) history of child psychiatry.

We have become accustomed to a high standard of production in publications from psychoanalytic sources, and this volume is no exception. It contains articles of varying character. Some are purely theoretical, while others contain more or less detailed analyses of particular symptoms, such as tic, enuresis, and reading disabilities. There is also a group of papers on the psychoses of childhood, and others are directed towards studying the ways of educating children in emotional experience both directly and indirectly through the various persons in the environment. Lastly there is a paper by the late Dr. Kate Friedlander on child guidance, to remind us of her pioneer creation of the first child guidance unit in this country inspired by purely psychoanalytic concepts.

In the face of this broad front it is out of the question to do more than give certain reflections about the position in child psychiatry which this book displays. As a representative volume on the present position in psychoanalysis it is somewhat deceptive; it is a retrenchment, and we find a gap which should be filled in by those trends in psychoanalysis that seem to open up new vistas.

From certain comments in the book, as well as from the absence of articles by some well-known child psychoanalysts, it appears that the editors of this volume have decided to reject out of hand the work of Melanie Klein and her associates, and the book suffers in consequence. There is also a lack of analytic grasp when we arrive at the psychoses in childhood, and, though there is a first class article by Spitz on anaclitic depression, it is psychiatric rather than analytic in outlook. This particular article is marred by the most peculiarly loose statements about several analysts, e.g. Mrs. Klein, Adler, Rank, Reich and Jung. I am not in any position to be certain about the others, but it is quite wrong to say that Jung assumes "... that human beings are born with a finished and complete psychic structure."

With so much to the credit of the editors it is a pity that this statement should have been allowed to creep in. One would have thought less of it were it not that psychoanalysts have too often proved unable to overcome the temptation to eject those who do not conform to the theoretical framework. In doing so they maintain a certain purity, but it is a phenomenon which makes the claim to scientific objectivity dubious. Indeed, the tendency of psychoanalysis to become a cult is still there, as it has always been. This book is an example of the value contained within the walls of the cult which are now, apparently, in the process of being rebuilt after partial demolition.

These general criticisms should not, however, prevent those interested in child psychiatry from getting hold of this book and reading it from cover to cover. In it they will find descriptions of much that they know, but at almost every turn there will be new material which can deepen their understanding of the infantile psyche. Without practical experience of an analytic kind the longer articles will be difficult to evaluate. Without some idea of the analytic process, the description of the psychic development of any given case always sounds somewhat incredible, but it cannot be said that any better method of presentation can be found.

Michael Fordham

### 1342 *Developmental Diagnosis: Normal and Abnormal Child Development. Clinical Methods and Pediatric Applications*

Arnold Gesell & Catherine S. Amatruda. Second edition, revised and enlarged. London: Hamish Hamilton Medical Books, 1947. xvi + 496 pages; 22 illustrations. 24 x 16 cm. £1 12s. 6d. [£1.625]

Part One: Principles and methods. (i) The development of behavior; (ii) the developmental examination of behavior; (iii) norms of development; (iv) conduct of the examination. Part Two: Problems of differential diagnosis; (v) Problems of high grade; (vi) low grade amentia disorders; (vii) the neurological diagnosis of infant behavior; (viii) cerebral injury; (ix) blindness; (x) deafness; (xi) prematurity; (xii) precocity; (xiii) environmental retardation; (xiv) clinical aspects of child adoption. Part Three: The protection of early child development. (xv) Diagnosis and guidance; (xvi) developmental pediatrics. Appendices. A. Examination technique. B. Growth

This is a book with a somewhat ambiguous title, but after perusal the reader is left in no doubt as to its pertinence. Briefly the title implies that by an objective study of certain behaviour reactions of an infant the maturity and organization of its neuromuscular system can be diagnosed and a developmental quotient obtained which will serve as a useful guide for prognosis.

At the Yale Clinic of Child Development Dr. Gesell and Dr. Amatruda have for a number of years made a systematic and extensive study of normal child development during the first three years of life, in particular the development of certain of the sensorimotor neurones associated with the head, eyes, mouth, arms and hands, ear, larynx, etc. As a result of their research the authors have devised a series of 'behaviour tests', arranged in nine age-groups, applicable to children between the ages of four weeks and three years. No elaborate apparatus is needed for carrying out these tests, the material required being such common objects as balls, cubes, rattles, bells, etc. The tests have been devised to cover the fields of motor behaviour, adaptive behaviour, language behaviour and personal-social behaviour. The purpose of the tests is to determine a child's behaviour development, from which information his Developmental Quotient (DQ) can be expressed as a percentage by using the formula:

$$DQ = \frac{\text{Maturity age}}{\text{Chronological age}} \times 100.$$

That the efficient carrying out of these behaviour tests is not as simple as the apparatus used might suggest is indicated by the fact that the Yale Clinic provides specialized courses of post-graduate training of one or two years' duration for paediatricists. It is interesting to note that at this course use is made of an extensive series of cinema records of infants' behaviour development at different ages.

Part Two of the book (over 200 pages) deals with such defects and deviations of development as amentia, endocrine disorders, blindness, deafness, cerebral injury and environmental retardation. The information given in the chapters dealing with amentia should not only be valuable to those medical officers who are called upon to ascertain the mentalities of young children, to whom the standard intelligence tests are hardly applicable, but also to paediatricians and others in preventing them from raising false hopes in the minds of the infants' parents.

Particularly interesting chapters are those entitled "Environmental Retardation" and "Clinical Aspects of Child Adoption". The former chapter discusses the importance of environmental factors and shows how any such factors that are adverse may lead to behaviour impoverishment which may be mistaken for unsubstantial hereditary endowment. It is a chapter which might advantageously be read by those responsible for Institutions for children.

The chapter on child adoption refers to the potential hazards both to the children concerned and their foster-parents, which hazards can largely be avoided by appropriate placing. Both over-placement and under-placement can be harmful. In this connexion the authors state that when the question is asked "Is it safe to adopt an infant?" the reply might well be "Safe for whom?" Several interesting cases are quoted to illustrate the important matters discussed in these chapters.

The book, which is an interesting one, contains a fund of information which is made most readable and vivid as a result of

the inclusion of a number of illustrative cases. It can well be recommended as a notable contribution towards the subject of clinical paediatrics.

R. Gamlin

### 1343 Psychotherapy in Child Guidance

Gordon Hamilton. New York: Columbia University Press; London: Geoffrey Cumberlege, Oxford University Press, 1947. xxii + 340 pages. 22 x 14 cm. £1 2s. [£1.1]

(i) Clinically oriented social casework; (ii) the diagnostic process in child guidance; (iii) the child who acts out his impulses; (iv) the anxious child; (v) the severely disturbed child; (vi) direct treatment in the therapeutic process; (vii) the therapeutically conditioned environment; (viii) treatment of young children; (ix) treatment of the older child; (x) treatment of adolescents; (xi) treatment of the family; (xii) preparation for psychotherapy in social work. Bibliography. Index.

The essential feature of child guidance is team-work whereby several specialists in different disciplines bring their combined knowledge and experience to bear on a child's behaviour problem, evaluate its causation and significance and formulate a programme of treatment. At its best such team-work produces results that cannot be equalled by any other method. At its worst it is a disjointed and discordant mixture of views and opinions where there is failure in harmonious integration.

In *Psychotherapy in child guidance* Professor Gordon Hamilton gives an excellent account of the evolution of child guidance as practised in the Clinic of the Jewish Board of Guardians in New York, who have solved the problems arising in team-work by giving the social worker the role of psychotherapist. The question formulated in the foreword by Dr. Ackerman, "Why does the caseworker assume the role of therapist, rather than the psychiatrist himself?" is nowhere answered; but one feels that the psychoanalytic orientation of this group of workers provides the key.

Although the "ivory-tower" psychology of the psychoanalyst is stated to be outdated, problems of co-operation and of group tensions arise constantly amongst psychoanalytic workers. There will be many who will disagree fundamentally with the approach and technique that Professor Hamilton outlines, but nevertheless the book, which is provocative and stimulating, should be widely read. Besides the specific contributions made to the practice of child guidance there is a great deal of valuable case material and sound common sense on the different needs of children and adults in the treatment situation. Because the child cannot by himself alter his environment, he must look to adults for assistance. Consequently "direct psychological treatment and environmental modification must remain two aspects of a single effort in helping children".

As one would anticipate, environmental factors are given proper weight throughout the book: "There is no substitute for income, housing, food, and shelter, and there is no therapeutic substitute for family relationships... 'Affect hunger' is as crippling as is starvation of the body." It would be invidious and unfruitful to select for quotation one more than another part, but the shrewd and practical comments which intersperse clinical accounts of cases illustrate the wide basis of experience upon which the theory is built.

Psychosomatic problems are given due weight, and while here and there constitutional factors, particularly as limitations, are stressed, they are for the most part underrated owing to the psychoanalytic bias in interpretation. On the other hand a bald statement that "the psychoneurotic... is always a sensitive child" requires qualification.

There is a timely warning against too much deep psychotherapy. "Insight", Professor Hamilton reminds us, "may not only be unsuccessful but may easily prove harmful". Stress is laid appropriately on the importance of dealing with the family as a whole, with full awareness of the tensions between parent and child:

... the family dynamics must be not only understood but also utilized in treatment... with one worker or two, as needed... The family situation in which the behavior is being manifested is the central social fact to be accepted... In child guidance... the past is active in the immediate present in a special way.

Professor Hamilton ends by giving some necessary warnings concerning the training required by a social worker who is to employ psychotherapy:

Training for psychotherapy in social work does not have the objective of training the worker to be a lay analyst, but to use the principles of psychoanalytical psychiatry in a social context... Not all competent case-workers will have interest in or aptitude for psychotherapy, so that careful

screening and vocational guidance are essential... There is no substitute for liking children and having a natural skill with them.

There is a useful, if predominantly American, bibliography and a well-documented index. The book may be recommended to all those associated with child guidance work, but more particularly to the experienced and the critically minded.

Alan Maberley

### 1344 Psychiatric Interviews with Children

Edited by Helen Leland Witmer. New York: The Commonwealth Fund; London: Geoffrey Cumberlege, Oxford University Press, 1946. vii + 443 pages; 6 illustrations. 26 x 17 cm. £1 5s. [£1.25]

Part I. Introductory comments. Part II. The cases. Part III. Comments in conclusion.

The outstanding difficulty in psychological medicine, particularly with regard to psychotherapy, is the impossibility of conveying the nature of a psychiatric interview. Attempts have been made to record such interviews by dictaphone and similar mechanisms, but they all seem to fail because they tend to flatten out all the emotional interplay which must be of the very essence of an interview of this kind. Nevertheless, this volume has great value in so far as it attempts to get the essence of the interview with the child in such a way as to reconstruct the contact existing between the physician and the child over a long period of time.

We must, however, make one qualification in speaking of psychotherapy or child analysis in connexion with the volume before us. The technique of treatment as practised by the participants in this work is a part of the evolution of the team method known as child guidance. This technique, in which the team, consisting of a psychiatrist, a social worker and an educational psychologist, work together in the elucidating of a given case, developed slowly but inevitably from the work of American psychologists. Starting with Adolf Meyer, the American school realized that psychiatry was a dynamic study and not an analysis of cold, intellectually constructed entities. Meyer's work underwent further and most significant developments with the acceptance of Freud's fundamental theories. It was now possible not only to see the patient, and particularly the child, as a product of inheritance and environment, but to see also that the patient was a world in himself of conflicting emotions attempting the work of adaptation to reality. It soon became evident that the understanding of the child could be made complete only by studying him in terms of his own language, the language of play. But even that alone was not sufficient to deal with the multitude of problems in family life, in which the child was not only the maker of his own neurosis, but was aided and abetted by the parents themselves. Child guidance technique is illustrated in this volume as an attempt to amalgamate the analysis of the child with the guidance of the parents. The method of handling parents has itself changed in the last twenty years. At first an effort was made to make the parent change the conditions of the child's life, but the more it became clear that the parents' psychological problems were in part responsible for the child's problems, the more inevitable it became that the interview with the parents by the social worker was itself at the very frontiers of therapy. Such discoveries, therefore, that the social worker makes, can now be utilized on the same psychological level as the discoveries that the psychologist makes with the child.

This volume has contributions from some of America's most distinguished child psychiatrists: Frederick Allen, Phyllis Blanchard, Lydia Daves, Hyman Lippman, Martha MacDonald, Beata Rant & Robert Young. Although one cannot but rest unsatisfied with these excerpts from interviews, a brave attempt has been made to bring to the reader the close interpersonal relationship which they set up in the course of the treatment, and also the close relationship which the clinic team always maintains between its members and the parents and the child. The volume is essentially a set of human documents, and although we cannot, and possibly ought not to expect clarified psychological concepts in each case, the writers of each section do bring to life the actual child, and this is perhaps as much as we can ask. Another type of book would be necessary for the detailed exposition of theories of the child's mental dynamics, but this would be scientific and less human, whereas this volume is human and does not claim to create a science.

Emanuel Miller

## CLINICAL MEDICINE

## 1345 The Background of Therapeutics

J. Harold Burn. London: Geoffrey Cumberlege, Oxford University Press, 1948. vi + 367 pages; 58 figures. 22 x 14 cm. £1 2s. 6d. [£1.125]

(i) Systems of medicine; (ii) reflex centre; (iii) the thyroid and thioracil; (iv) the anaphylaxis and histamine; in syphilis; (viii) the malar aggranulocytosis, and folic acid; (x) iron and calcium; (xi) plasma protein and the liver. Oedema and digitalis; (xii) the steroid hormones; (xiii) acetylcholine in skeletal muscle. Myasthenia gravis; (xiv) advances in neurology; (xv) analeptics, including pressor agents; (xvi) theories of anaesthetic action; (xvii) alloxan diabetes; (xviii) statistics explained. Index.

In the chain which connects laboratory science and clinical medicine the weakest link is often that between laboratory and clinical research. Professor Burn has succeeded in strengthening this link by producing a book which illustrates the application of laboratory investigation and scientific principles to the treatment of disease. He stresses the great importance of patient investigation under carefully controlled conditions in the laboratory as a prelude to research work in the clinical field; but it is doubtful whether clinicians would entirely agree with his dictum that two to five years' training in a laboratory is an essential prelude to clinical investigation. Clinical acumen, which is indispensable to the clinical research worker, is a quality which is not automatically conferred by pure scientific ability, and cannot be acquired without years of clinical experience and practice. Perhaps the nearest approach to the ideal method would be for the clinician to spend some part of every working day in laboratory work in addition to clinical work.

The book covers many aspects of therapeutics and each chapter has been cleverly arranged to illustrate the application of non-clinical research to the problems of clinical medicine. A few criticisms may, however, legitimately be made. In discussing the use of thioracil compounds the author states that patients with nodular goitres respond less well than those with primary thyrotoxicosis. Although this statement was made by more than one authority in the early days of thioracil therapy, many workers now agree that patients with nodular goitres respond as well as those with primary thyrotoxicosis, if not better. In Chapter IV, local chemotherapy is discussed at length, but no mention is made of the value of systemic chemotherapy in the treatment of infected wounds and burns, or of the danger of sensitization to sulphonamide compounds and the production of penicillin-resistant organisms when local application is used. The mode of action of anaphylaxis and of antihistamine substances is fully discussed in Chapter V; therapeutic trials have now, however, thrown more light on the clinical application and limitations of the latter. Professor Burn rightly sounds a note of caution in the use of amphetamine in the treatment of obesity, but in the opinion of the reviewer the doses suggested are too high. It is doubtful if more than 10 mg. daily should ever be given, and higher dosage is not likely to be more effective. This drug should never be given to patients with moderate or severe hypertension.

The effectiveness of folic acid in restoring to normal the blood picture in patients with megaloblastic anaemia is well described in Chapter IX. Initially it was thought that folic acid would supplant liver extract in the treatment of pernicious anaemia but, as we have found from clinical follow-up studies, the former agent fails to arrest sub-acute combined degeneration of the spinal cord, and may even exacerbate this condition. The story of folic acid illustrates admirably the importance of integrating scientific research with clinical observation.

In view of recent statements that digitalis acts in congestive heart failure by lowering venous pressure, many clinicians will welcome Professor Burn's emphasis on its action in increasing the force of contraction of heart muscle, and depressing conductivity. There is, however, little clinical advantage in using strophanthin rather than digoxin for rapid intravenous therapy.

The treatment of Addison's disease by implantation of desoxycorticosterone acetate (DOCA) into the subcutaneous tissues is mentioned in Chapter XII and a figure of 375 mg. is quoted for a single implantation. This dosage is dangerous, and the reviewer has seen hypertension with left ventricular failure occur in a patient whose implant was increased from 100 mg. to 200 mg. Calculations based on the daily requirements of injected DOCA and the amount of DOCA supposedly provided

daily by the implant are probably entirely fallacious, and increasing the size of the implant does not materially increase or prolong its effectiveness.

One of the best chapters is that which deals with myasthenia gravis, curare, and the transmission of nervous impulses to muscle. There is also a useful chapter on statistics and a fascinating account of various systems of medicine.

This is a most important book because, apart from the valuable information which it contains, it emphasizes the mutual interdependence of the research physiologist, pharmacologist, and clinician. Professor Burn is to be congratulated on writing so lucid and readable a work, which should be read by all who practise and teach clinical medicine.

J. F. Goodwin

## 1346 Progress in Clinical Medicine. By Various Authors

Edited by Raymond Daley & Henry G. Miller. London: J. & A. Churchill Ltd., 1948. xi + 356 pages; 22 text-figures; 15 plates. 24 x 16 cm. £1 1s. [£1.05]

(i) The control of infections; (ii) venereal diseases; (iii) tropical medicine; (iv) gastro-intestinal disorders including liver diseases; (v) metabolic disorders; (vi) cardiovascular diseases, (vii) renal diseases; (viii) diseases of the blood; (ix) diseases of the chest; (x) diseases of the nervous system; (xi) endocrine disorders; (xii) psychosomatic medicine; (xiii) the chronic rheumatic diseases. Index.

This volume is the work of a group of specialists, each with wide experience in his chosen field; its purpose is to give an authoritative account of the major developments of the last few years. The articles include a select list of references to the current literature, which should be of considerable value. On the whole, the authors have succeeded admirably in their purpose.

A review of penicillin is welcome since it includes a short but comprehensive account of the position with regard to aerosols, whereas the account of the subject of streptomycin must necessarily be already a little out of date by the time the reader is reached. The position of penicillin in venereal disease is authoritatively discussed and a method of treatment recommended. The standing of mepacrine and paludrine in anti-malarial therapy is reviewed, and the modern treatment of the dysenteries and parasitic infections given. Avery Jones, in dealing with gastrointestinal disorders, describes in masterly fashion the oft-neglected subject of oesophageal hiatus hernia and then goes on to a review of the present standing of gastroscopy, in which its advantages and drawbacks are clearly outlined. Less might well have been written on ulcers in a work of this type, whereas the summary of the vast literature on gastrointestinal bleeding and its treatment will be welcome to most readers. George A. Smart reviews disorders of metabolism, devoting most of the space to the subject of diabetes. The chapter on cardiovascular disease deals with several fairly recent advances, such as the surgery of congenital heart disease, but fails to mention the important advances made with the aid of the cardiac catheter or modern methods of electrocardiography. Renal and blood disorders are reviewed, and in the chapter on the latter, Martin C. G. Israëls gives a welcome list of the indications for the performance of sternal marrow puncture. Modern trends in the treatment of pulmonary tuberculosis are described. A discussion on intervertebral discs and electroencephalography, amongst other subjects, are dealt with in a chapter on nervous diseases. An excellent chapter on psychosomatic medicine, perhaps the best part of the book, with a comprehensive analysis of recent work in this field, is written by Henry G. Miller, while two short chapters are devoted to the fields of endocrinology and rheumatology.

This book is certainly one of the better of the symposia which aspire to introduce the specialist to advances in fields of medicine other than his own.

G. Loewi

## 1347 The Modern Management of Gastric and Duodenal Ulcer

Edited by F. Croxon Deller. Edinburgh: E. & S. Livingstone Ltd., 1948. 227 pages; 57 figures. 23 x 16 cm. £1

(i) Applied anatomy and physiology; (ii) pathogenesis; (iii) clinical pathology; (iv) symptoms; (v) clinical examination; (vi) special investigations: (a) radiology

(b) gastric analysis (c) occult blood test (d) gastric aspiration (e) gastroscopy; (vi) differential diagnosis; (vii) the diagnosis of the complications of gastric and duodenal ulcers; (ix) the diagnosis of malignancy; (x) the decision on treatment; (xi) strict medical therapy; (xii) the indications for surgical treatment; (xiii) the surgical operative details; (xiv) the complications of operations for gastric and duodenal ulcer; (xv) anaesthesia for gastric operations; (xvi) details of ancillary diagnostic methods. Epilogue. References. Index.

The editor of this monograph writes in the "Epilogue" that, in the treatment of gastric and duodenal ulcer, "Team-work is essential." The volume is evidently a reflection of such team-work in practice, for the five specialist contributors, like the editor, are members of the staff of Southend General Hospital. The editor and Dr. R. Sleight Johnson deal with the medical aspects, Mr. Rodney Maingot and Mr. A. K. Monro write the surgical chapters, the section on radiological diagnosis is by Dr. H. C. H. Bull, and that on anaesthesia is by Dr. J. Alfred Lee. The result stands as a vindication, if any is needed, of the value of team-work in the handling of this difficult problem.

All aspects of the subject are considered, including anatomy, physiology, pathology, radiology and anaesthesia, but the emphasis lies on the clinical problem and the whole is presented essentially for the clinician, who will find it both readable and educative whether he be general practitioner, physician or surgeon. The work is throughout practical, including for example precise details of techniques of investigation, of alternative diets for medical therapy, and of the operative methods advised. There is, however, no over-simplification of the problem and the difficulties are presented and discussed in a helpful way.

The epithet "modern" in the title proves to be justified and this fact will increase the value of the book to those clinicians who find it difficult to keep pace with the current output of papers on peptic ulcer in the journals. There is, for example, a description and balanced estimate of the operation of vagotomy.

The volume fills the present need for a review of its subject so well that criticism would be out of place, but the omission of description and discussion of the methods of estimating the night secretions of the stomach may be regretted. It is to be hoped that some mis-statements of fact will be corrected in another edition, as that *enterogastrostomy* is a stimulant of gastric secretion (p. 12) or that: "Anatomically, the lesser curvature differs from the remainder of the stomach in that it bears the acid-producing mucosa . . ." (p. 45).

The book attains a high standard of production and illustration, and includes a useful list of references and an index.

A. G. R. Lowdon

### 1348 Hodgkin's Disease and Allied Disorders

Henry Jackson & Frederic Parker. New York: Oxford University Press; London: Geoffrey Cumberlege, 1947. x + 177 pages; 15 plates. 29 x 19 cm. £2 5s. [£2.25]

(i) Hodgkin's disease: 1. History, etiology, incidence. 2. Pathology. 3. Symptoms and course. 4. Involvement of certain organs. 5. Involvement of certain other organs. 6. Clinical diagnosis. 7. Treatment and prognosis; (ii) reticulum-cell sarcoma: primary in bone; (iii) lymphocytoma and lymphoblastoma; (iv) lymphosarcoma; (v) giant-follicle lymphoma; (vi) plasmacytoma; (vii) endothelioma. Index.

This monograph is a combined clinical and pathological study of a large series of personal cases of Hodgkin's disease, together with an exhaustive and instructive discussion of every aspect of the disease. There are shorter descriptions of the related primary lymphadenopathies which accentuate the well-recognized clinical and pathological individuality of Hodgkin's disease itself and are of value in its differential diagnosis.

The nomenclature used in the description of Hodgkin's disease will be somewhat strange to English readers. It is based on two assumptions: first, that the pathological background of Hodgkin's disease is a reactive inflammatory hyperplasia of mesenchyme to an unknown infective agent—for this reason the lesion is described as a granuloma; second, that this process may take on all the characteristics of a destructive and infiltrating sarcomatous growth which, as it clearly arises on the basis of the granulomatous lesion, should be called "Hodgkin's sarcoma". The evolution of the fully developed granuloma with visceral involvement is said to have two distinct phases, "Hodgkin's paraneoplasia" and "Hodgkin's granuloma", the former describing

the period usually called "early Hodgkin's disease", in which only the peripheral glands and spleen are involved, the latter being used for the period when the disease becomes generalized and the liver, bone marrow, skin, lungs and bowel strongly tend to be affected. The term "Hodgkin's paraneoplasia" is considered to be preferable to "early Hodgkin's disease" in that this stage often has a duration of several years, in exceptional cases up to ten. The term "lymphoma" is used freely in describing some of the other primary lymphadenopathies. This confusion of terms will persist, and is likely to become still more confusing as long as these diseases are described on a basis of histological structure and until we gain more precise knowledge of their etiology. Meanwhile the position calls for the exercise of patience and tolerance. In the case of this monograph the reader will quickly grasp what the authors mean by "Hodgkin's paraneoplasia", and having translated this into his own nomenclature he will certainly profit by the accounts of their experience and their clearly written and critical discussions. On the other hand, the reader may belong to the school which some time ago cast "Hodgkin's sarcoma" into the outer darkness. He should read this monograph and decide for himself, on the evidence submitted, whether this was justifiable.

C. Hodfield

### 1349 Jaundice: its Pathogenesis and Differential Diagnosis

Eli Rodin Movitt. New York: Oxford University Press; London: Geoffrey Cumberlege, 1947. xvi + 261 pages; 23 figures; 2 colour plates. 24 x 16 cm. £2 2s. [£2.1]

Part I. (i) The anatomy of the liver and the biliary tract; (ii) the physiology of the liver; (iii) the metabolism of the bile pigment; (iv) the pathogenesis of jaundice; (v) diagnostic procedures; (vi) differential diagnosis of jaundice—general principles. Part II. (vii) Hemolytic jaundice; (viii) parenchymatous jaundice—acute and subacute hepatitis; (ix) parenchymatous jaundice (continued)—chronic hepatitis. Carcinoma; (x) obstructive jaundice. Appendix. Index.

This book is intended as a practical text for the general physician and the gastro-enterologist. In many ways, however, it fails to fulfil this purpose. As indicated by the title the scope is limited to the pathogenesis and differential diagnosis of jaundice. Much important recent work on the liver, is, therefore, omitted. In particular the relation of diet to diseases of the liver and the valuable contributions to hepatic physiology by hepatic venous catheterization are not included. Treatment is not mentioned. The text does not seem full enough to satisfy the present need for an up-to-date reference book of liver diseases, neither is it concise enough to be used as a students' manual.

The book is divided into two parts. The first part deals with the anatomy and physiology of the liver along the usual textbook lines. There is little attempt at critical evaluation of the statements included. As the book deals specifically with jaundice, the author's opinion on the Van den Bergh reaction and its limitations and the relation between direct and indirect bilirubin would be welcomed.

The second part is devoted to largely clinical descriptions of the various diseases giving rise to icterus. These accounts will be in the main helpful to the clinician; they are very readable. However, in this section also there are grounds for criticism. The outmoded term "catarrhal jaundice" is retained in the chapter on parenchymatous icterus. Possible syringe contamination by the causative virus is not included in the etiology of the jaundice occurring during arsenotherapy for syphilis. The table (p. 182) which attempts to distinguish between epidemic and homologous serum jaundice is rather optimistic.

References to the literature are included at the end of each chapter. However, in the text, the authors are rarely mentioned by name. As the titles of the papers are not quoted this makes further study by the reader very difficult. The American literature is well covered up to the date of publication (1947). References to European work are scanty.

The book is well produced; misprints are few. In view of the present shortage of books on the liver it is unfortunate that it cannot be more enthusiastically recommended.

Sheila Sherlock

## DENTAL SCIENCE

### 1350 Oral and Dental Diseases: Aetiology, Histopathology, Clinical Features and Treatment. A Textbook for Dental Students and a Reference Book for Dental and Medical Practitioners

Hubert H. Stones. Edinburgh: E. & S. Livingstone Ltd., 1948. xix + 896 pages; 926 illustrations. 25 x 18 cm. £4 10s. [£4.5]

(i) Congenital malformations of the jaws and associated parts; (ii) the effects of endocrine disorders on the development of the jaws and teeth; (iii) the effects of nutritional deficiencies on the teeth and jaws; (iv) osteodystrophies involving the jaws; (v) eruption and resorption of the deciduous dentition: associated pathological conditions; (vi) eruption of the permanent dentition: associated pathological conditions; (vii) anomalies in number, size and form of the teeth; (viii) abnormalities of structure—hypoplasia; (ix) malocclusion of the teeth and maldevelopment of the jaws; (x) traumatic occlusion. Functionless teeth. The width of the periodontal membrane; (xi) attrition, abrasion and erosion of the teeth; (xii) the effects on the dental tissues of procedures used in operative dental surgery; (xiii) injuries to the teeth due to violence; (xiv) the aetiology of dental caries; (xv) bacteriology of dental caries; (xvi) the histopathology and clinical features of dental caries; (xvii) reparative and regressive processes in the dentine and pulp; (xviii) bacteriology, inflammation, necrosis and gangrene of the pulp; (xix) acute local periodontitis and acute periapical abscess; (xx) chronic local periodontitis, periapical granuloma and chronic periapical abscess; (xxi) resorption of the teeth; (xxii) cementum: abnormalities associated with its formation; (xxiii) acute infections of the face and neck that may be of oral causation: abscess and cellulitis; (xxiv) saliva; (xxv) calculus; (xxvi) stains and discoloration of the teeth; (xxvii) bacteriology of the mouth and of chronic gingivitis and parodontal disease; (xxviii) chronic gingivitis and parodontal disease (periodontitis); (xxix) stomatitis and allied diseases of the oral mucosa; (xxx) stomatitis and allied diseases of the oral mucosa (*continued*); (xxxi) stomatitis and allied diseases of the oral mucosa (*continued*); (xxxii) stomatitis and allied diseases of the oral mucosa (*continued*); (xxxiii) chronic oral sepsis and its relation to systemic diseases. Focal infection; (xxxiv) inflammation of the maxillary sinus. Involvement during dental operations; (xxxv) periostitis, osteomyelitis and necrosis of the jaws; (xxxvi) traumatic maxillo-facial injuries; (xxxvii) inflammatory lesions of the mandibular joint; (xxxviii) neuralgia; (xxxix) cysts of odontogenic origin. Composite and connective tissue odontomata; (xl) oral inclusion cysts; (xli) oral tumours; (xlii) diseases of the salivary and oral mucous glands. Author index. Subject index.

Other publications have dealt with diseases and injuries of the teeth and their investing tissues, the oral mucosa and the jaw. Few recount so lucidly the etiology, histopathology and clinical characteristics of the lesions considered or explain, as this does, how rational therapeutic measures may be based on a sound understanding of the nature of the injuries and diseases which the dental surgeon may encounter. A feature of this new textbook, which is intended for dental students and for dental and medical practitioners, is the number of excellent illustrations, which include a wealth of photomicrographs as well as monochromatic and coloured clinical photographs. Especially valuable are the references to more recent research both in this country and elsewhere, while the balanced views afforded on controversial issues will assist those who find the conflicting evidence and opinions on some aspects of oral pathology bewildering. The admirable chapters on periodontitis and gingivitis and on traumatic maxillo-facial injuries will be found particularly helpful, as will those on cysts, tumours and diseases of the oral mucosa. Especially commendable is the consideration given to the effects of everyday operative procedures, which have not been crowded out by the more obscure although picturesque rarities. In compiling this textbook, which we are confident will be of the greatest use to both student and practitioner, the author has drawn on his own extensive experience both as teacher and clinician and has embodied much of his own research. His broad conception and sound pathological approach materially enhance the value of a work which will be, we are certain, warmly received.

The book is well printed and presented; the text is both concise and comprehensive.

R. V. Bradlaw

## DERMATOLOGY

### 1351 Modern Trends in Dermatology

Edited by R. M. B. MacKenna. London: Butterworth & Co. Ltd., 1948. xiv + 432 pages; 32 figures. 25 x 17 cm. £2 2s. [£2.1]

(i) The dermatology of yesterday, to-day, and to-morrow; (ii) the anatomy of the skin; (iii) physiology and functional pathology of the skin; (iv) dermatology

and nutrition; (v) the biochemistry of skin; (vi) the influence of the sex hormones on the skin and pilosebaceous system, with a discussion of the aetiology of 'seborrhoeic' eruptions; (vii) bacteriology; (viii) the autogenous disinfection of the skin; (ix) parasitology in relation to dermatology; (x) mycology in relation to dermatology; (xi) psychological aspects of dermatology; (xii) occupational dermatoses; (xiii) dermatological problems in tropical and sub-tropical areas; (xiv) necrobioses, atrophies, scleroses, infiltrations and accumulations in the skin; (xv) the prevention of cutaneous diseases, excluding modern trends in therapy; (xvi) the rehabilitation of cutaneous disease; (xvii) on the use of statistics.

For this symposium the editor has gathered contributions from both sides of the Atlantic, and furthermore dermatologists are outnumbered two to one. Consequently the outlook on the various aspects of the specialty is wide, which is right and proper; for, as F. A. E. Crew says in his chapter on the prevention of cutaneous diseases, excluding industrial maladies, "The plain fact is that the dermatologist must either be much more than a skin specialist or else find neither satisfaction nor serenity in his vocation." The first chapter, on the dermatology of yesterday, today and tomorrow, reflects the wide-ranging vision of J. H. Stokes, always a potent stimulator of thought.

The chapter on anatomy incorporates the newer knowledge which has been acquired through experimental methods, a modern trend in a subject so long static; while the complementary one on physiology and functional pathology shows that there is still much to be ascertained in this field. The article on nutrition deals mainly with the vitamins and the one on biochemistry outlines the action of enzymes on the skin. Parkes Weber's article on necrobioses, atrophies and scleroses also has mainly biochemical connexions. Although biochemistry has established relations with dermatology for a much shorter period than have bacteriology, mycology and parasitology, it is the chief modern trend in dermatology; but these other subjects also have their latest advances satisfactorily correlated here.

Psychosomatic medicine is represented by articles on the psychological aspects of dermatology and on rehabilitation. Earlier in the book the reader will note the following warning: "Care must be taken, therefore, before ascribing a person's physical symptoms wholly to his psychological state, since the latter may well depend upon a metabolic error, the correction of which may completely change his mental outlook."

This book, intended for dermatologists and senior students of dermatology, is the most interesting one on the subject that has appeared in the last decade. The non-dermatologist will also find much to interest him, and the book will certainly dispel any long-rooted prejudices that the specialty is merely an affair of peddling lotions and ointments. It is a pleasure to find that overworked term allergy reduced to its proper perspective; on the other hand it is astounding to find no reference in the index to itching or pruritus, nor is this condition dealt with under physiology or functional pathology.

As the majority of articles are written by those not specializing in skin diseases, dermatologists will naturally find a few statements with which they disagree, but they will be thankful to have this book. They must read, re-read and ponder on it.

G. W. B.

### 1352 The Skin Diseases. A Manual for Practitioners and Students

James Marshall. London: Macmillan & Co. Ltd., 1948. xi + 363 pages; 214 figures. 22 x 14 cm. £1 10s. [£1.5]

(i) Anatomy and physiology of the skin; (ii) pathological changes in the skin; (iii) symptomatology of skin diseases; (iv) diagnosis; (v) principles of treatment; (vi) congenital abnormalities; (vii) physical dermatoses; (viii) the infectious fevers; (ix) pyogenic infections; (x) bacillary infections; (xi) syphilis; (xii) acquired syphilis (primary stage); (xiii) acquired syphilis (secondary stage); (xiv) acquired syphilis (tertiary stage); (xv) prenatal or congenital syphilis; (xvi) treatment of syphilis; (xvii) cutaneous tuberculosis; (xviii) lupus erythematosus; (xix) diseases due to viruses; (xx) diseases due to animal parasites; (xxi) diseases due to fungi; (xxii) the papulo-squamous eruptions; (xxiii) toxic dermatoses of epidermal origin; (xxiv) toxic eruptions of dermal origin; (xxv) drug eruptions; (xxvi) psychological aspects of skin diseases; (xxvii) pruritus, neurodermatitis, dyshidrosis and prurigo; (xxviii) dermatoses of vascular origin; (xxix) atrophies and degenerations; (xxx) reparatory disturbances; (xxxi) hyperkeratoses, dyskeratoses and hyperplasia; (xxxii) vitamin deficiency diseases; (xxxiii) diseases of the cutaneous appendages; (xxxiv) tumours of the skin. Index.

This manual is designed for students and is written simply and practically. Whilst emphasizing the commoner conditions, it attempts to cover the whole field of dermatology, but the value of cursory references to numerous rarities in a book of this type is doubtful. The chapter on diagnosis contains a topographical

list of diseases, illustrated by diagrams which are very helpful to the beginner, and the chapter on treatment is clear, with simple but adequate prescriptions. It is not, however, very practical to advise penicillin, given every three hours, day and night, to a total of 60-80 injections, for furunculosis.

The best section both for matter and for illustrations (except for histological ones) is that on syphilis, which is obviously based on the author's own wide observation and experience in treatment. The present reviewer approves of the inclusion of chapters on infectious diseases and on the psychological aspect of skin disease. There are numerous statements to which exception might be taken; these concern the use of radium for port-wine stains, the necessity for disinfection of the clothes after benzyl benzoate treatment of scabies, the hourly spraying with penicillin in impetigo, and the dosage of 50 mg. of benadryl every four hours for urticaria, etc. There is also no mention of elastoplast in the treatment of gravitational ulcers. Despite these criticisms, the general practitioner will find this a useful and understandable book.

F. F. H.

## ENDOCRINOLOGY

### 1353 Major Endocrine Disorders

S. Leonard Simpson. Second edition. London: Geoffrey Cumberlege, Oxford University Press, 1948. xxii + 552 pages; 89 figures. 22 x 14 cm. £2 2s. [£2.1]

Section I. The pituitary: A. Physiology. B. Clinical. Section II. The adrenals: A. Physiology. B. Clinical. Section III. The thyroid: A. Physiology. B. Clinical. Section IV. The parathyroids: A. Physiology. B. Clinical. Section V. The gonads: A. Physiology. B. Clinical. Section VI. The pancreas: A. Physiology. B. Clinical. Appendices. Reference index.

There seems to be a grim determination in the minds of publishers and authors to make ordinary readers, what is termed in America, "endocrine conscious". There have appeared recently quite half a dozen works on clinical endocrinology and Dr. Leonard Simpson's *Major endocrine disorders* now reappears after ten years, as a second edition. The most exhaustive work on clinical endocrinology is the book entitled *Klinisk endokrinologi* by Hermann Nielsen of Copenhagen. This work is in three volumes of which the first was published in 1938, the second in 1941, and the third in 1942. As the text is in Danish it is only of limited value and it is therefore with great interest that one takes up an English work which covers roughly the same field.

Dr. Simpson has used the space at his disposal very ingeniously and the book is certainly an essential as a reference work for anyone interested in this subject. It is obvious to the reader that Dr. Simpson is mainly interested in the purely clinical aspect. His descriptions and illustrations are very good; he has also taken great trouble in most cases to read and present to the reader the original descriptions of the diseases.

If one were to criticize, one would like to have seen a more detailed account of the physiology and biochemistry of the endocrine glands and of their products. One cannot help feeling that the reader who did not possess fairly good knowledge of these matters would find Dr. Simpson's descriptions rather meagre. To give a specific example: the reviewer was unable to find any clear-cut description of what is really meant by 17-ketosteroids. One can imagine that many general physicians will turn to such a book as this with the hope of finding an explanation of this familiar term. If one looks in the index, one finds references to excretion of 17-ketosteroids in various conditions, but there is no statement as to what they are or how they are determined, and so forth. Let us hope that Dr. Simpson in a future edition will devote a section of his book to a description in simple language of the more technical side of the subject for the general reader.

If he were asked to pick out the best chapter, the reviewer would mention in particular the one on the adrenals. Here the author has given a concise and clear picture of this extremely difficult subject; he has described adrenal physiology and biochemistry in some detail, thus enabling the reader to appreciate fully the very excellent summary of the clinical applications of this knowledge.

E. C. Dodds

### 1354 Endocrinology of Neoplastic Diseases. A Symposium by Eighteen Authors

Edited by Gray H. Twombly & George T. Pack. New York: Oxford University Press; London: Geoffrey Cumberlege, 1947. vi + 392 pages; illustrations. 24 x 16 cm. £3

(i) Tumors in experimental animals receiving steroid hormones; (ii) experimental investigations concerning the role of the pituitary in tumorigenesis; (iii) the endocrine effects of pituitary tumors; (iv) ovarian tumors with sex hormone function; (v) endocrine factors in the origin of tumors of the uterus; (vi) the relationship of hormones to diseases of the breast; (vii) the effect of sex hormones on skeletal metastases from breast cancer; (viii) benign hypertrophy and carcinoma of the prostate; (ix) the endocrine treatment of cancers of the prostate gland; (x) the relationship of hormones to testicular tumors; (xi) adrenal cortical tumors—physiologic considerations; (xii) hormonal tumors of the adrenal; (xiii) the endocrine activity of thyroid tumors and the influence of the thyroid hormone on tumors in general; (xiv) the endocrine aspect of enlargements of the parathyroid glands; (xv) hyperinsulinism in relation to pancreatic tumors; (xvi) the endocrinologic aspects of tumors of the pineal gland. Index.

It is never quite easy to review a book which has been written by many different individuals. In the present instance the task is somewhat simplified by the fact that every one of the eighteen contributors is a recognized authority on the subject about which he writes. The book is founded on a series of articles which first appeared in *Surgery* in 1944 and have since been revised and brought up to date. In the course of the sixteen articles of which the book is composed, consideration is given to: (i) the role of the pituitary in the causation of tumours, (ii) the neoplastic effects of certain hormones, (iii) the excessive production of hormones by some neoplastic tissues, (iv) the treatment of tumours by the administration of hormones, (v) the urinary excretion of hormones as an aid to the diagnosis of certain tumours. Organs which receive detailed attention are the pituitary, ovary, testis, mamma, prostate, adrenal, thyroid, parathyroid, pancreas and pineal body; and adequate consideration has been given to appropriate laboratory work performed on animals. One or two slips can be found in this as in any other symposium. For example the "nearly always" on line ten of page 215 may be compared with the seventeen out of twenty-five (68%) in lines 30, 31 of page 220. However, the lapses from unbroken perfection are negligible when the general excellence of the book is regarded; in fact some of the contributions, especially the one by Robert A. Moore on benign hypertrophy and carcinoma of the prostate, might be used as a model of the way in which surgical problems should be presented.

This is a first-class book, rich with information, and everyone interested in the subject with which it deals will find it indispensable.

Harold Burrows

## FORENSIC MEDICINE

### 1355 Taylor's Principles and Practice of Medical Jurisprudence. Volume I

Originally written by Alfred Swaine Taylor. Tenth edition edited by Sydney Smith, with a complete revision of the legal aspect by W. G. H. Cook and of the chemical aspect by C. P. Stewart. London: J. & A. Churchill Ltd., 1948. viii + 723 pages; 48 figures; 1 plate. 25 x 16 cm. £2 5s. [£2.25]

(i) Introduction; (ii) medico legal responsibility in the examination of the person alive and dead; (iii) constitution and functions of General Medical Council—malpractice; administration of anaesthetics: quackery: neglect; (iv) identification of living persons and human remains; (v) death: its signs and changes that take place in the body after death; (vi) apparent death: premature burial; (vii) general inferences to be drawn from a dead body apart from the cause of death; (viii) legal presumption of death and of survivorship; (ix) wounds and personal injuries (general); (x) the examination of blood stains; (xi) firearm wounds; (xii) death from lightning and from electrical currents; (xiii) deaths connected with cold and heat—spontaneous combustion: vitriol throwing; (xiv) starvation; (xv) asphyxial deaths—suffocation: drowning: strangulation: hanging; (xvi) suicide; (xvii) life insurance—general and accident: general life insurance; (xviii) insanity—general, and in relation to the law. Index.

This volume is essentially a book of reference, being too extensive for the undergraduate, and as such it enjoys an unchallengeable position in the realm of medicolegal literature. Eighty-three years have passed since Alfred Swaine Taylor first introduced his book and, despite the fact that he was responsible for only the 1st and 2nd editions, it is a great tribute to his subject-matter, and to the three editors who have since handled the work,

that it is still in demand. In some respects it is unfortunate that both volumes of the present edition could not be published simultaneously.

Professor Sydney Smith and Dr. W. G. H. Cook are to be congratulated on the present volume. Its arrangement has been altered, certain sections have been entirely rewritten, and a great deal of new material has been included. The chapters dealing with medicolegal responsibility in the examination of the person alive or dead, with malpraxis and medical negligence, and with asphyxial deaths, are particularly good.

English rather than Scottish law is emphasized throughout, and in this respect the book is somewhat less useful to the Scottish reader. It seems a little unfortunate that the arrival of the new edition, four years after its predecessor, could not have been slightly retarded in view of the advent of a considerable amount of new legislation with a medicolegal bearing. Such a course would have permitted inclusions and obviated the tendency to have the new book out of date from its start. The preface states, in relation to the National Insurance (Industrial Injuries) Act, 1946:

The new Act has been dealt with very briefly in its medico-legal applications, which is all that is possible or necessary at the present stage; it would seem, however, that many of the defects of the former legislation (Workmen's Compensation Acts) have been remedied.

The subject-matter relating to the Workmen's Compensation Acts occupies less than a page, and that relating to the National Insurance (Industrial Injuries) Act only 13 lines. Information regarding industrial diseases, apart from eight lines on their relation to the Workmen's Compensation Acts, appears to be entirely absent. It is also noted that the term "Certifying Surgeon" is adhered to, although this term has been replaced by the designation "Examining Surgeon".

The short account of dactylography is rather unsatisfying. One feels that this subject lies more within the province of the finger-print expert than of the medicolegal specialist; if it is to be dealt with at all in works pertaining to medical jurisprudence, this should be done with the assistance of an appropriate expert.

In dealing with the matter of the identification by examination of bones, the question of the overlap of male and female characters in the pelvis, an important and not infrequent finding, might have been discussed. The more recent work and views on the vagaries of the obliteration of cranial sutures also deserves mention.

The table on p. 410, giving the average sizes of blood corpuscles of different animals, could well have been omitted. While such matters may be of undoubted biological interest, serological tests have made them of little value in the identification of blood as a laboratory routine.

The paucity of illustration (48 figures and 1 plate in a volume of 723 pages), and their poor quality and unsuitability, is perhaps the greatest deficiency of this volume. Some chapters suffer particularly, the one on wounds being a notable example. The six drawings of fibres on p. 121, and the drawing on p. 403 representing haemin crystals, are hardly what one would expect to find in such a book; photomicrographs are almost universally employed and are far superior.

Despite these criticisms, the book as a whole is well balanced textually, has been authoritatively revised, and provides a mine of information, much of which is not to be found in the shorter textbooks. The legal aspects of the subject are clearly set out and the stamp of the expert is upon them. Those interested in medicolegal matters owe a debt of gratitude to the editor and to those associated with him for the painstaking task they have undertaken and performed so capably. This first volume of the 10th edition of Taylor can be confidently assessed as the best so far published.

John Glaister

## HISTOLOGY

### 1356 Gynaecological Histology

Josephine Barnes. London: Harvey & Blythe Ltd., 1948. xii + 242 pages; 162 figures. 22 x 14 cm. £1 10s. [£1.5]

(i) The body of the uterus; (ii) the cervix; (iii) the Fallopian tube; (iv) the ovary; (v) the vagina; (vi) the vulva; (vii) pregnancy. Index.

The author states that this book has been written with the object of providing a simple guide to the histology of the normal

and abnormal tissues encountered in gynaecological practice. This object has certainly been achieved. For senior students preparing for the final or postgraduate examination the book should prove very useful. The arrangement of the book is unusual but effective. The subject is divided into seven chapters: each deals with a particular part of the female genital tract, and contains a survey of the normal or pathological histology followed by illustrations, in fact photomicrographs, showing the appearances of the tissues described. Beneath each photomicrograph is a short but adequate account indicating the chief features. The subject matter is lucid, concise and matter of fact but nevertheless sound. There appear to be few important omissions.

In the chapter dealing with the endometrium of the uterine body, no reference is made to the mitoses which are found in the glands and stroma in the proliferative phase. The well-known decidual reaction in the stroma which occurs at the close of the premenstrual period and which is such a definite feature in many sections is not mentioned, though a brief allusion is made to it in the last chapter.

It is essential that in a book of this type the illustrations be good. There are 162 illustrations and most of them are good. Some of those dealing with the neoplasms of the ovary are excellent. There are, however, several which are not very convincing and could be replaced with advantage. Among these may be mentioned both the illustrations showing tuberculous endometritis and the one of carcinoma of the uterine body with squamous metaplasia.

This is an unusual but attractive book and there are many to whom it may prove very helpful.

## LACTATION

### 1357 Breast Feeding. A Guide to the Natural Feeding of Infants

F. Charlotte Naish. London: Geoffrey Cumberlege, Oxford University Press, 1948. viii + 151 pages; 20 figures. 19 x 13 cm. 10s. 6d. [£0.525]

(i) The mind of the mother; (ii) the physiology of lactation; (iii) ante-natal preparations; (iv) the first week; (v) the second week; (vi) 'the danger weeks' (3rd to 6th); (vii) established breast feeding. Appendix: The feeding of twins and triplets; (viii) weaning; (ix) breast trouble; (x) contra-indications to breast feeding and indications for weaning; (xi) breast feeding without suckling. Index.

This excellent little book is entirely practical in outlook and almost entirely practical in content; accounts of the theories involved are limited to the shortest necessary to give an understanding of events in lactation and breast-feeding.

It seems obvious that the natural way of feeding a child is likely to be the best, and statistics showing the incidence of gastro-enteritis and respiratory diseases most emphatically confirm the value of breast-feeding. The argument is sometimes heard that bottle-fed babies are those who are more weakly from birth and consequently more susceptible to disease; this has a small element of truth in it but it still remains likely that such infants would fare better if kept on the breast. The fact is, however, that breast-feeding is becoming less frequent in this country simply because an increasing number of mothers do not wish to carry it out.

Dr. Naish wastes no time in railing against social tendencies but attacks those problems that can be remedied immediately. She blames the doctor in many cases for failing to use his authority to keep the baby on the breast, when others, of whom the grandmother is a particularly frequent offender, are anxious to discredit the mother's efforts in order that by bottle-feeding they may obtain control of the child; incidentally, this unconscious desire is shown all too often by the nursing staff in hospital. In addition to this, surely, the doctor's failure has been that too little attention has been paid by the profession as a whole, to preparing the mother mentally and physically, from the first months of pregnancy, for feeding her infant. The author gives clear and exact instructions as to the management of breast-feeding; she describes the common causes of failure stage by stage and suggests what should be done to prevent and to remedy any faults, but early in the book emphasizes that adequate feeding is more important than entire breast-feeding for its own sake.

The whole account is brief, full of common sense and obviously written by someone who has a thorough knowledge of the subject and of the requirements of the people for whom the book was intended, as well as an understanding of the needs of mother and child.

There are a few points which it hardly seems fair to criticize, since they do not affect the practical advice given: but it is a little misleading to speak of the fatty consistency of colostrum, although the author's meaning is clear—and does the digestion of cow's milk really require more energy than the digestion of human milk?

This book is so useful that it is to be hoped that it will be possible to publish it later, not in the form of a textbook to be kept in libraries, but as a cheap paper-backed booklet which every medical student can be expected to buy, however short of money he may be; it must certainly be in the possession of all doctors and nurses who have charge of nursing mothers.

A. P. Norman

## MEDICAL PHILOSOPHY

### 1358 *The Harveian Oration: the Structure of Medicine and its Place Among the Sciences*

F. M. R. Walshe. Edinburgh: E. & S. Livingstone Ltd., 1948. 26 pages. 19 x 13 cm. 1s. 6d. [£0.075]

The Harveian Oration has been the occasion of many memorable utterances. Amongst these Dr. Walshe's philosophical discourse takes a high place. He is a master of the telling and arresting phrase, and is a powerful and persuasive advocate. His apology for "essay[ing] a theme so far transcending my capacity" will be dismissed summarily by his readers; rather will they look for a more detailed treatment from him of "those intellectual instruments and methods by which alone the confused data of our experience as physicians can be transmuted into a more or less coherent body of ordered knowledge", even though it disturbs the intellectual sloth of some of his contemporaries.

Harvey's work is used to illustrate the untenable dichotomy of the notions of observation and experiment, and art and science, except on the basis of arbitrary definitions. Dr. Walshe's treatment underlines Locke's statement that "every man has so inviolable a liberty to make words stand for what ideas he pleases, that no one hath the power to make others have the same ideas in their minds that he has, when they use the same words that he does." He stresses that Harvey's discovery of the circulation of the blood shows that there can be no fruitful experiment without reason. And he is (and what student of biology can fail to be?) a whole-hearted advocate of Smuts' holism! A Gothic cathedral is more than the sum of its individual stones, and man is greater than the sum of his systems, or tissues, or organs.

Dr. Walshe claims no originality for the topics he discusses; indeed, many of them are the common themes of texts on scientific method. But it is well that these should be restated on such an occasion and in so provoking a manner. This is not to suggest that the effort is beyond criticism. For example, when Dr. Walshe writes: "The process of observation is inextricably bound up with the entertainment of ideas, and with an emotional ferment that is felt as the subjective sense of importance, as interest, or what Quakers speak of as 'concern'", we sigh for the simplicity of language of Shakespeare, whose lover saw "Helen's beauty in a brow of Egypt." It would, moreover, be arguable that when Dr. Walshe regards "the clinician as passing the indeterminate frontier between observation and experiment when he devises a test to evoke signs in his examination"—e.g. eliciting a knee jerk—he himself falls victim to that unguarded use of abstraction and "false simplification" which he so rightly condemns. These minor criticisms, and each reader will name his own, do not detract from the merit of the work. Dr. Walshe has in earlier writings established his claim to a secure place amongst those who have contributed to the philosophy of medicine in our time. His Harveian Oration enhances his reputation in this neglected field.

Henry Cohen

## MEDICAL RESEARCH

### 1359 *Medical Research in War. Report of the Medical Research Council for the Years 1939-45*

Medical Research Council. London: His Majesty's Stationery Office, 1948. (Committee of Privy Council for Medical Research.) 455 pages. 24 x 15 cm. 7s. 6d. [£0.375]

Report of the Committee of Privy Council for Medical Research. Report of the Medical Research Council: (i) introduction; (ii) wounds and injuries; (iii) war diseases; (iv) therapeutics, including penicillin; (v) nutrition in war-time; (vi) personnel research; (vii) health research in industry; (viii) special emergency services; (ix) miscellaneous research and other activities supported or assisted by the Council during the war; (x) war publications; (xi) the National Institute for Medical Research; (xii) the preparation and maintenance of biological standards; (xiii) external research establishments and scientific staff; (xiv) research work aided by grants; (xv) postgraduate studentships and research fellowships; (xvi) conclusion. Index to subjects of research. Index to institutions. Index to personal names.

Because of war conditions, the Medical Research Council did not publish annual reports from 1939 to 1945. This volume remedies the deficiency and gives a very full account of the Council's activity during that critical period. The Council was called upon to give advisory and administrative assistance to various Government Departments and to the fighting Services in the application of the latest scientific knowledge to the practical conduct of affairs; they also directed and sponsored research devoted to solving those medical problems that were dictated by the urgencies of war. The present report reflects the way in which the whole activity of the Council was redirected along channels designed to yield direct contributions to the war effort. It is not surprising, therefore, to find that the research projects sanctioned by the Council were mainly concerned with practical problems rather than with basic scientific research.

The investigation of the properties of penicillin and the development of penicillin therapy was perhaps the most important project with which the Council was concerned. The work on penicillin<sup>1</sup> dates, of course, from its discovery by Sir Alexander Fleming in 1929, and the subsequent work done by Fleming, Florey, Chain and others. The Council, together with the Rockefeller Foundation of New York and the Nuffield Trust, contributed to the cost of a comprehensive programme of investigation at Oxford which was drawn up in 1939 before the war began. The advent of war greatly accelerated this programme: animal experiments were followed by clinical trials at Oxford and measures of the most vigorous kind were taken to bring penicillin into large-scale production, with the results that are now generally known. American collaboration, especially in the matter of production, was close and effective; the programme resulted in penicillin being available in the latter part of the war, in time to have a tremendous effect in reducing the mortality rate of casualties.

A large volume of work was accomplished in other fields. The practical problems of the treatment of war wounds, burns, traumatic shock, and head injuries were the subject of intensive investigation. The work of the War Wounds Committee was instrumental in assessing various modes of treatment and in establishing and standardizing treatment along the most effective lines.

Extensive work was also done by the Council on the problems associated with nutrition in wartime, rationing, accessory food factors, and nutrition in the Forces. Personnel research, especially related to the needs of the Army, Navy and Air Force, was also carried on, as was the study of personnel problems in industry under wartime conditions (cf. "Some Problems of Personnel Research", symposium in *Brit. med. Bull.* 1947, Vol. 5, No. 1). Extensive research in health problems in industry was undertaken. The publication of the *Bulletin of War Medicine* by the Council gave wide distribution of the results of its work.

Basic research into problems of radiobiology, bacteriology, and other fields was also maintained, though not, of course, on the same scale as during the pre-war years. The work of the Permanent Standards Commission of the League of Nations was

<sup>1</sup> [Cf. *The chemistry of penicillin*, edited by Hans T. Clarke, John R. Johnson & Sir Robert Robinson. Princeton: Princeton University Press; London: Geoffrey Cumberlege, Oxford University Press, 1949. This recent report on a collaborative investigation under the joint sponsorship of the Office of Scientific Research & Development, Washington, D.C., and the Medical Research Council, London, will receive a full review in the next number of the *British Medical Bulletin*.—Ed.]

1360-1361

largely carried on during the war by the MRC, in the preparation and maintenance of biological standards. Large stocks of the international standards of drugs, vitamins and hormones were kept in several depots in Britain, and, under the varying exigencies of war, were despatched to Geneva, Canada and the USA for safe-keeping.

With the termination of hostilities, the Council's work has again been re-orientated, and is now proceeding along normal peace-time lines. The present report will be of considerable interest to all those who were in any way associated with wartime research, and forms a lasting record of the achievements of British medical research during the war.

D. F.

# 1360 The Rh Blood Groups and their Clinical Effects

P. L. Mollison, A. E. Mourant & R. R. Race. London: His Majesty's Stationery Office, 1948. (Medical Research Council Memorandum No. 19.) 74 pages. 24 x 15 cm. 1s. 6d. [£0.075]

- (i) The Rh groups; (ii) clinical considerations; (iii) Rh testing.

This monograph is greatly to be welcomed, as it supplies a much-needed summary of the principal facts about the Rh factor and the clinical conditions in which it is of importance. The work is divided into three parts:

- I The serological analysis of the Rh groups, the Rh antibodies and the gene frequencies in England.
- II Clinical considerations of diagnosis and treatment.
- III The indications for, and technique to be employed in, Rh tests.

Section I (by Race) provides one of the clearest expositions of the Rh antigens and antibodies yet given in English, Fisher's notation being used throughout, and the clarity is enhanced by the avoidance of any alternative system of nomenclature in the text; the equivalents in Wiener's system are, however, set out in Table V. It is thus emphasized from the beginning that Rh positive means the possession of Fisher's antigen D, and that all who display only the allele d are to be counted Rh negative irrespective of any other antigen which they may possess. There-irrespective of the other components of Fisher's linked-gene theory after the resulting 8 Rh complexes and their various introduced and the newer knowledge about the genotypes are displayed. The newer knowledge about antigenic variants of the elementary antigens is only briefly outlined, as is proper in a monograph designed to emphasize the more important rather than the more highly esoteric aspects of this work. Since this publication, further analyses of variants have been published by Race and his co-workers for those specially interested in this advanced field. Race's exposition of the genetical basis of the Rh groups is very easy to follow, though time may show it to be an over-simplification. Nevertheless it is useful in conveying a stimulating blood. Section II (by Mollison) outlines first the importance of Rh in transfusion practice and emphasizes the frequency groups in transfusion by transfusion of Rh positive blood and ease of immunization by transfusion of Rh negative blood to Rh negative recipients, a matter not yet sufficiently appreciated by many clinicians. The importance of immunization in pregnancy is next dealt with, and the seriousness of the risk of Rh positive mothers to Rh negative mothers is emphasized, as only by such practice can the risk of inadvertent administration of Rh positive blood to Rh negative mothers be minimized. Mollison also points out the clinical importance of the sub-groups of Rh and the dangers of classifying as Rh positive recipients who show the C or E antigens; such persons must also be excluded from the Rh negative donor panels in case their blood should be administered to an Rh negative recipient immunized against C or E. This matter has become even more important since the discovery that a proportion of apparently Cde (R') and Cde (R'') individuals possess a modified form of D, the so-called Du variant, the administration of which to immunize the recipient against D. This section concludes with a note on advice to the parents of affected children about future pregnancies and this will be appreciated by the harassed practitioner in dealing with anxious parents. The proportion of fathers likely to be homozygous is given as 75 per cent but this applies only to small families (two or three children); when haemolytic disease

appears only later in a larger family the proportion of heterozygous fathers rises, but of course these cases are not only less numerous but also the loss of subsequent children is less important than in the former group. The interpretation of the findings of Rh antibodies in the mother's blood during pregnancy is discussed, but the most valuable section is that on the differential diagnosis and the assessment of the severity of haemolytic disease in the newborn. Mollison's views on these matters are pretty generally accepted in Great Britain and the methods outlined might well become a standard guide to clinical practice. The directions for the transfusions of infants are extremely good and make it clear that in experienced hands are exsanguination transfusion is no more difficult or hazardous than simple transfusion; it appears, indeed, to have several advantages on the grounds of ease and simplicity. Mollison very properly directs attention to the added difficulties of trying to cannulate the internal saphenous vein by using instruments designed for operations on adults; it cannot be too strongly urged that the treatment of the newborn necessitates the provision of a set of fine instruments of suitable size which should be reserved for this purpose. Section III (by Mourant) gives precise and explicit directions for the performance of Rh tests, which will be a boon to most laboratory workers. The circumstances demanding such tests are clearly defined and all the practical points are lucidly explained. A timely plea is made for the co-operation of clinicians in securing adequate supplies of testing sera, without which the work would come to an end. The different kinds of tests used in typing the red cells are described; in the next edition of this memorandum, it would be helpful to give further directions about the detection of the weakly reacting forms of D so that they may be excluded from Rh negative group; meanwhile, in the selection of donors, any with the C or E antigens should be excluded and the use of double-agglutinin sera for this purpose is explained.

The preparation of anti-human-globulin serum (Coombs' reagent) is described and the direct and indirect Coombs' tests are fully detailed. Alternative methods of detecting Rh antibodies and the value of direct matching tests are discussed, but the impossibility of devising any single test which will satisfy all conditions is clearly pointed out. A brief note is included on the effects of cholera filtrate and of trypsin on the agglutination of red cells but these special methods are not advised for routine use. The methods of absorbing unwanted agglutinins from test-sera are briefly stated, but the use of purified A and B substance is omitted, absorption with red cells of appropriate groups or with saliva being recommended. In view of Morgan's work this omission is surprising, and might well be remedied in any future edition.

As a whole this monograph is a fine production and is timely; as a summary of the very real contributions to knowledge in this sphere made by British workers. If it has avoided controversial matters of nomenclature by ignoring them, the presentation of facts is thereby clarified, and it will undoubtedly greatly facilitate the dissemination of knowledge on this highly complex and somewhat esoteric subject.

D. F. Coppel

# 1361 Symposia of the Society for Experimental Biology. Number I. Nucleic Acid Biology.

Society for Experimental Biology. Cambridge: Cambridge University Press, 1947. vi + 290 pages; 29 figures; 18 plates. 25 x 16 cm. £1 15s. [£1.75]

- (i) The structures of nucleic acids; (ii) structure and synthesis of nucleotides; (iii) the biological synthesis of purine compounds; (iv) the macromolecular behaviour of nucleic acids; (v) X-ray studies of nucleic acids; (vi) the distribution of nucleic acids in tissues; (vii) bacterial nucleic acids and nucleoproteins; (viii) a study of techniques for the cytochemical demonstration of nucleic acids and some components of proteins; (ix) ribonucleic acid and the vital staining of cytoplasmic vacuoles in animal cells; (x) the relations between nucleic acid and protein synthesis; (xi) protein and nucleotide metabolism in the nerve cell under different functional conditions; (xii) nucleic acid in nerve-cell regeneration; (xiii) tissue changes in mice treated with pentose nucleotides; (xiv) histochemical observations on nucleic acids in homologous normal and neoplastic tissues; (xv) nucleic acids in the cell and the embryo; (xvi) the action of enzymes on chromosomes; (xvii) the function of deoxyribose-nucleic acid in the cell nucleus; (xviii) nucleic acid and the chromosomes; (xix) the experimental modification of nucleic acid systems in the cell.

The Society for Experimental Biology of Great Britain has adopted the custom of holding meetings from time to time in a university centre, where several days are devoted to the discussion

of some suitable subject of general biological interest. Such a symposium was held in Cambridge in July 1946 when the subject for discussion was "Nucleic acid", and the papers given at this meeting were published in the form of Number I of the *Symposia of the Society for Experimental Biology*. They are the products of some twenty different authorities on the subject, of several nationalities, and they cover a very wide range. The purely chemical aspects of the nucleic acids are discussed by Gulland, by Jordan, by Lythgoe & Todd, and by Astbury, while the more biochemical aspects are dealt with by Kalckar, by Davidson and by Stacey. Cytochemical contributions are made by Danielli and by Dustin. An important paper by Caspersson summarizes the work of the Stockholm school on the relation of nucleic acid to protein synthesis. The nucleic acids of nervous tissue are discussed by Hyden and by Bodian, of tumours by Stowell and of embryonic tissues by Brachet, while Parsons, Gulland & Barker describe the effects of pentose nucleotides on living tissues. Problems of the cell nucleus, chromosomes and genetics are discussed by Catcheside & Holmes, by the Stedmans, by Darlington and by Koller.

This book, therefore, contains information on nucleic acids which will be of interest to a large number of readers whose own spheres of work may vary from synthetic organic chemistry to pure cytology. But the chemist may well profit by reading of the biological implications of the nucleic acids, just as the biologist may derive benefit from information about the more chemical aspects.

The nucleic acids have aroused so much interest of recent years that a publication of this sort in which information covering a very wide range is collected together must inevitably be of great value. The Society of Experimental Biology is to be congratulated, not only on organizing the symposium and arranging for authorities in the nucleic acid field from different parts of the world to meet together, but also for initiating a new series of review publications on topics of wide biological interest.

The scientific reader at the present day is faced with the problem of keeping up to date not merely with original papers but with a rapidly increasing number of reviews and annuals in which original papers are summarized. But where a review is in fact a report of the deliberation of a group of experts who meet together to discuss their common interest from different angles, its publication is both justified and to be commended.

## NEUROLOGY

### 1362 Critical Studies in Neurology

F. M. R. Walshe. Edinburgh: E. & S. Livingstone Ltd., 1948. xv + 256 pages. 22 x 14 cm. 15s. [£0.75]

(i) The anatomy and physiology of cutaneous sensibility; (ii) the giant cells of Betz, the motor cortex and the pyramidal tract; (iii) on the mode of representation of movements in the motor cortex, with special reference to "convulsions beginning unilaterally" (Jackson); (iv) on the notion of the "discrete movement" in willed motion; (v) on the rôle of the pyramidal system in willed movements; (vi) the integration of medicine.

For many years Dr. Walshe has had a wide public, for the obvious reason that he not only strikes a fresh note, but is always critical in a stimulating way. He does fine work both in his lectures and in his writings in enlarging our understanding of some of the problems which he is turning over in his mind. At one time his thought seems to pierce the proposition like lightning; at another he is able to exercise the patience of Job in awaiting a true interpretation of his facts. This pattern, or type of approach, is found in only a few of our pioneers, perhaps notably those with the soundest psychological training; the facts are one thing, available to all accurate workers, but the correct interpretation requires much critical thought, a relatively simple matter for some, but quite beyond the capacity of many. As Dr. Walshe says in his foreword:

There should be a wide measure of agreement upon the crying need for critical thought in neurology. By no other intellectual weapon can we hope to deal effectively with what Trotter has called 'the mysterious variability of the false'; a variability that we owe in part to the uncritical spirit in which some write and others read original papers . . .

The papers which comprise this book have all been published during or after 1942, five of them in *Brain*. First is the essay on the anatomy and physiology of cutaneous sensation. This

is a lengthy review of a fascinating subject where some famous giants of the past, Head, Rivers, Trotter, and more recently, Sherrington, form stepping-stones over which the author proceeds with care and respect, yet not without criticism. Next comes his study of the giant cells of Betz, the motor cortex, and the pyramidal tract. Here he describes carefully the earlier researches to determine the origin of the pyramidal tract, showing that even the remarkable progress in forty years still leaves many questions unsettled, and emphasizing again the limitation of the cellular approach when it is considered alone. Then follows "On the Mode of Representation of Movements in the Motor Cortex, with Special Reference to 'Convulsions Beginning Unilaterally' (Jackson)", a shorter essay which debates the experimental and the clinical evidence concerning localization. The two relatively brief chapters which follow are both on the theme of "willed motion", the second one being an elaboration of Walshe's paper at the Neurological Section of the International Conference of Physicians in London, September 1947. In this the author offers valid arguments showing the defects he sees in the now widely held conception of pyramidal function.

The last paper is entitled "The Integration of Medicine" and is reprinted from the *British Medical Journal* (1945), 1, 723. It is the thoughtful and challenging oration given to the Medical Society of London in May 1945. Perhaps this chapter might have preceded the others, not only because it seems to indicate so clearly the author's approach and philosophy, but also because it brings the reader into step at a moderate pace, and sharpens his critical faculties to enable him to enjoy the great wealth of material contained in the more definitive chapters. Now gathered together in this easily accessible volume, these papers will be widely read or re-read. Let us hope that Dr. Walshe is contemplating further exercises for our benefit.

J. K. S.

### 1363 Headache and Other Head Pain

Harold G. Wolff. New York: Oxford University Press; London: Geoffrey Cumberlege, 1948. xxii + 642 pages; 154 figures. 24 x 16 cm. £3 3s. [£3.15]

(i) Pain-sensitive structures within the cranial cavity; (ii) headache associated with changes in intracranial pressure; (iii) headache and brain tumor; (iv) headache from distention of cerebral and pial arteries; (v) the cerebral circulation and the headache of subarachnoid hemorrhage; (vi) the extracranial blood vessels as pain-sensitive structures; (vii) inflammation of cranial arteries as a source of headache and other pain; (viii) headache in the migraine syndrome; (ix) the relation of life situations, personality features, and reactions to the migraine syndrome; (x) modification of intensity and frequency of headache in the migraine syndrome; (xi) vascular accidents with migraine headache; (xii) headache associated with arterial hypertension; (xiii) 'cephalgias' and 'atypical neuralgias' of the face and head; (xiv) the teeth as sources of headache and other pain; (xv) the nasal, paranasal, and aural structures as sources of headache and other pain; (xvi) the eyes as a source of headache and other pain; (xvii) muscles of the head and neck as sources of headache and other pain; (xviii) chronic post-traumatic headache; (xix) typical or major neuralgias ('tic douloureux'), postinfectious neuralgias, neuritis, and 'intractable pain'; (xx) the action of analgesics; (xxi) summary. Clinical differentiation. Addendum. Index.

This publication consists of a very full account of the research that has been carried out by Wolff and his co-workers, during the past fifteen years, into the mechanism of the various types of headache. Those who keep abreast with advances in medicine will have read many of the author's papers on the subject as and when they have appeared in various American medical journals, and will already be reaping the benefit of the vast amount of new knowledge which Wolff's work has brought to the understanding of a common and important symptom.

Nevertheless, to have the whole of this work in one volume is a most valuable addition to medical literature and the book will not only be much used for reference but will also be regarded as a model of well-planned and logical clinical research. It is too long to hold any great appeal to the undergraduate and to him the author's contribution to the *Text-book of medicine* by Cecil & Kennedy, which contains all the essential information in abbreviated form, is especially recommended, but there is no doubt that it is a book which every neurologist, general physician and medical library should have.

As with most American publications, the paper and printing are beyond reproach and the reproduction of the diagrams is excellent. In addition the author's style is most readable and lucid and his practice of including a brief summary at the end of each chapter has much to commend it. That he has included in his investigations the headaches of hypertensive, otological,

rhinological, ophthalmic and dental origin shows that the author is in no sense of the word a "pure" neurologist, and greatly adds to the value and comprehensiveness of the work.

The only serious criticism that can be made is that too little reference is made to headache of psychogenic origin. There can be no doubt that this is the commonest form of headache for which medical aid is sought and though many such cases arise from prolonged spasm of the muscles of the scalp and neck, which mechanism the author has investigated very fully and described very clearly, there remains a large number that cannot be so explained. It is probable, however, that the elucidation of such cases lies more within the ambit of the psychiatrist than of the neurologist.

The author makes a valiant attempt to introduce some order into the chaos of nomenclature, thought and therapy that surrounds the various forms of atypical facial and migrainous neuralgia. However, in view of the fact that such conditions are by nature almost entirely subjective in their manifestations, it appears likely that the future will bring the descriptive separation of more and more "new" types, with appropriate speculation as to their mechanism and advice regarding their cure.

A. G. W. Whitfield

## NURSING

### 1364 Report of the Working Party on the Recruitment and Training of Nurses

Ministry of Health, Department of Health for Scotland & Ministry of Labour and National Service. London: His Majesty's Stationery Office, 1947. v + 122 pages. 24 x 15 cm. 2s. 6d. [£0.125]

(i) Method of approach; (ii) number of nurses; (iii) structure of the nursing profession; (iv) intelligence of nurses; (v) estimated intake and loss of trained nurses; (vi) estimated intake and wastage of student nurses; (vii) wastage during training; (viii) the training of nurses—the present position; (ix) the training of nurses—a new system; (x) some implications of the new scheme of training; (xi) selection of student nurses; (xii) organisation and administration; (xiii) effects on staffing of converting to a three-shift system and student status; (xiv) the assistant nurse; (xv) summary of main conclusions. Note by the Chairman. Note by Dr. J. Cohen. Appendices: (i) references; (ii) percentile norms for the progressive matrices test; (iii) statistics relating to intake and wastage of student nurses in Great Britain; (iv) selection for senior posts in hospitals; (v) number of nurse training schools; (vi) length of present training courses; (vii) nursing techniques; (viii) "post-graduate" education; (ix) supervision of nurses' health; (x) nursing the chronic sick; (xi) mental nursing.

### Working Party on the Recruitment and Training of Nurses. Minority Report

Ministry of Health, Department of Health for Scotland & Ministry of Labour and National Service. London: His Majesty's Stationery Office, 1948. vi + 78 pages. 24 x 15 cm. 1s. 6d. [£0.075]

(i) The problem of estimating the nursing needs of the community; (ii) the inadequacy of opinion as a basis for policy in the nursing field; (iii) the value of research as a basis for planning the nursing services; (iv) the measurement of the effectiveness of nursing care; (v) the productivity of nurses; (vi) conclusions, recommendations and acknowledgements. Appendices: (i) references; (ii) relationship between duration of stay of patients in hospital and nurse staffing ratios; (iii) extracts from statements or letters sent by a sample of ex-student nurses; (iv) number of chronic sick and aged infirm in public assistance institutions and municipal hospitals in England and Wales at 31st August, 1946; (v) number of occupied beds and full-time nurses and midwives (male and female) employed in civilian hospitals in Great Britain at mid-1947; (vi) growth of the nursing and midwifery professions in England and Wales.

These Reports summarize the findings of a Working Party appointed in January 1946 to review the position of the nursing profession. The Report represents the views of Sir Robert Wood (the Chairman), Miss D. C. Bridges, Miss E. Cockayne, and Dr. T. D. Inch. One member of the Working Party, Dr. J. Cohen, found himself unable to concur, and has presented a Minority Report.

The Working Party enquired into the length and type of training desirable to equip nurses to fulfil their tasks, the annual intake of students required, the means of selecting these and the measures needed to reduce wastage in training. The available literature and previous reports on these subjects were carefully studied; extensive field studies in over 200 hospitals were carried out; and representative nurses of all grades employed in every branch of

the profession were interviewed. A "job analysis" of the work done by nurses in training was undertaken.

The Working Party found that the wastage during training was a key point in the enquiry: excluding failures at the final examinations and excluding nurses employed in mental hospitals, this was estimated at 36%. Some of this was found to be due to unsuitable temperament and therefore reflects faulty selection of students, but impartial investigation showed that discontent and frustration were cogent factors. It was found that discipline was often too harsh and unreasonable, and that the amenities of life of those in training and their hours of work all required reform. In interviews with student nurses by the Working Party, complaints were said to be "not the vague complaints of a discontented minority but the conclusions of a statistical survey."

Based on job analysis studies, the Working Party concluded that a two-year course of training for all nurses would be adequate, with provisional registration at the end of two years, followed by a further year of supervised practice before licence to practise was given. In effect, this is a training for three years, with the last year free from academic study. Eighteen months to two years would cover training in all branches of nursing, the final six months of the two years to be taken in one special branch. This would give a uniform title (State Registered Nurse) and qualification for all nurses. The period of training for student nurses would be based on a five-day week of 40 hours, with six weeks' annual leave. There was a strong recommendation that the finance of nurse training should be independent of hospital finance. All student nurses should continue to receive free tuition with board residence or an allowance in lieu and a suitable allowance for personal expenses.

It was also advised that a three-shift system of work in hospitals should be instituted. To give effect to this, and to allow the student nurses to take full student status, would require an estimated increase of 22,000 to 24,000 trained nurses and some 14,000 nursing orderlies. It was thought that to provide for existing needs and training reforms a force of not less than 120,000 and possibly 125,000 trained nurses would be needed. It was considered impossible to determine the number of additional staff required for the expansion of the National Health Service.

Dr. Cohen found it impossible to sign the Report, since in his view its recommendations failed to take sufficient account either of the relation between the planning of nursing and the other health services and the planning of the nation's labour resources as a whole, or of the extent to which methods employed in psychological research can provide a scientific basis for determining nursing and medical staffing ratios or determining the length of training periods for nurses. He feels that we have yet to discover the optimum number of beds per thousand population and the optimum number of nurses required to look after them; these things should be not matters of opinion but matters of fact ascertainable by scientific investigation.

He argues that "the task of nurses and doctors alike . . . is, presumably, to speed the patient's recovery", and takes as the economic criterion of nursing effectiveness the duration of the patient's stay in hospital. In an investigation of 260 voluntary<sup>1</sup> hospitals he found that, on the whole, this was shorter in well-staffed hospitals. This evidence supplies him with a *prima facie* case for increasing the number of nurses in general hospitals. Few people, however, will agree with the basic assumption on which all this is founded—namely, that the duration of the patient's stay in hospital is a satisfactory objective measure of the task of nurses and doctors. In fact, the length of stay is affected by many factors other than the ratio of staff to patients. Apart from the type of illness, it varies with the custom of the hospital, its facilities for investigation, treatment and after-care, with the whims of doctors and the pressure of the waiting list, to say nothing of the individual patient's reactions to hospital environment and medical treatment.

In summary, the Working Party's Report is a welcome document. The "job analysis" represents a new way of discovering facts by objective investigation. Its main shortcomings are its failure to secure the necessary data to answer the question, "What

<sup>1</sup> 'Voluntary' used in this sense "means not carried on for profit and not provided by a local or public authority" (*The National Health Service Act, 1946, annotated* . . . S. R. Speller, p. 126, London, 1948). Since the inauguration of the National Health Service, voluntary hospitals have been incorporated in the State medical service.—[Ed.]

is the proper task of a nurse?", and its failure to indicate from where the desirable candidates for training as nurses are to come. Nevertheless, the Report has stated the problem and it is up to the Ministries concerned, the present nursing profession and those who are to be nursed, to find out the proper answers.

The well-being of the country depends on the proper answers being found.

## OPHTHALMOLOGY

### 1365 *Lehrbuch der Augenheilkunde*

Edited by M. Amsler, A. Brückner, A. Franceschetti, H. Goldmann & E. B. Streiff. Basel: S. Karger, 1948. xx + 858 pages; 342 illustrations; 4 tables. 25 x 17 cm. 85 Sw. fr.

I. Allgemeiner Teil. (i) Untersuchungsmethoden; (ii) allgemeine Symptomatologie; (iii) Auge und Gesamtorganismus; (iv) Vererbung und Auge; (v) soziale Fragen in der Augenheilkunde; (vi) allgemeine Therapie. II. Spezieller Teil. (vii) Anatomie; (viii) Physiologie des Auges; (ix) das Glaukom; (x) Verletzungen; (xi) Krankheiten der Bindehaut; (xii) Krankheiten der Hornhaut; (xiii) Krankheiten der Lederhaut; (xiv) Krankheiten der Uvea; (xv) die Pupille; (xvi) Krankheiten der Linse; (xvii) Krankheiten des Glaskörpers; (xviii) Krankheiten der Netzhaut; (xix) Krankheiten des Sehnervens; (xx) Krankheiten der Sehbahn; (xxi) Krankheiten der Augenlider; (xxii) Krankheiten der Tränenorgane; (xxiii) Mollitätsstörungen des Auges; (xxiv) Krankheiten der Orbita. III. Augensymptome bei Allgemeinerkrankungen. (xxv) Augensymptome bei inneren Erkrankungen im weiteren Sinne; (xxvi) Augensymptome bei Frauenkrankheiten; (xxvii) Augensymptome bei chirurgischen Erkrankungen; (xxviii) Augensymptome bei Zahnkrankheiten; (xxix) Augensymptome bei Geisteskrankheiten; (xxx) Augensymptome bei Tropenkrankheiten; (xxxi) Augensymptome bei Hautkrankheiten; (xxxii) Augensymptome bei Hautkrankheiten; (xxxiii) Augensymptome bei Hals-, Nasen- und Ohrenkrankheiten. Sachregister.

This textbook of ophthalmology is intended for the student and for the general practitioner. In format and size it resembles the well-known textbooks of Axenfeld and of Fuchs, which have not been readily available for some time. Ophthalmology in Switzerland is very much alive and in this book Swiss ophthalmologists, and also Professor Weve of Utrecht, give a sound presentation of Continental teaching. Like every new book it has the advantage of being free from dead wood, which is so difficult to cut out from revised editions of older textbooks. More space is given to the basic sciences than usual; thus, out of some 800 pages, anatomy and embryology occupy nearly 90 pages, genetics and physiology some 50 pages each, and pharmacology and physical medicine some 40 pages. The chapter on genetics appears to be too detailed for the clinician, both in its theoretical and in its clinical aspects, but the importance of genetics is certainly brought home, even if such fine distinctions as the differential diagnosis of retinitis punctata albescens from fundus albino-punctatus cum hemeralopia are beyond the scope of those for whom the book is intended.

Clinical ophthalmology is lucidly presented and the results of modern methods of investigation are included. In the chapter on glaucoma the importance of the disease is emphasized by statistics showing its incidence, its relation to sex and the influence of weather in the occurrence of acute attacks. Though gonioscopy is not mentioned by name, descriptions and illustrations of the angle are given. Enlargement of the blind spot is given as the first change in the field; this differs from Traquair's teaching. In the chapter on muscles, diagnosis is mostly based on the double-image test with the red-green glass, and apparently major amblyoscopes and the prism-and-cover test are not popular. A printing error in the diagnostic table of muscle palsies needs correction. In the chapter on chemical burns, Denig's operation is advocated and a useful test for the vitality of the damaged conjunctiva is described; amniotic membrane grafting is not mentioned. The chapter on eye and general diseases, together with that on genetics and the many references to general medicine dispersed throughout the book, emphasize an aspect of ophthalmic teaching not well covered by the older texts.

The careful presentation both of text and illustrations makes the book stimulating reading; it is more than the foreword claims for it.

M. Klein

### 1366 *The Practice of Orthoptics*

G. H. Giles. London: Hammond, Hammond & Co. Ltd., 1947. 366 pages; 67 figures. 22 x 14 cm. £1 10s. [£1.5]

Part I. Introduction to the practice of orthoptics. (i) The basis of orthoptic treatment; (ii) routine refractive examination; (iii) the refractive error in squint and heterophoria; (iv) the recognition of unfavourable cases of strabismus; (v) the recognition of favourable cases of strabismus—routine examination (1); (vi) the routine examination (2); (vii) the selection of orthoptic cases of strabismus; (viii) heterophoria—detection and measurement; (ix) the selection of heterophoria cases suitable for orthoptic training; (x) the measurement of the fusional reserves; (xi) the mental effort; (xii) the psychological approach to squint treatment. Part II. The clinical practice of orthoptics. (xiii) The treatment of concomitant strabismus in outline; (xiv) the treatment of concomitant strabismus in detail; (xv) amblyopia, occlusion, and abnormal retinal correspondence; (xvi) the treatment of strabismus in young children; (xvii) the treatment of special types of strabismus; (xviii) the orthoptic treatment of horizontal heterophoria; (xix) the orthoptic treatment of hyperphoria, cyclophoria, and convergence insufficiency; (xx) the use of prisms and lenses in orthoptic practice; (xxi) the orthoptic treatment of service candidates; (xxii) naturopathic methods: a comparison with orthoptics. (xxiii) Glossary. Appendix I. Statistical survey of 116 orthoptic cases. Appendix II. Table of stages in treatment of strabismus. Appendix III. Diagnostic table—paralysis of the motor muscles. Bibliography. Index.

Although the author gives a great deal of useful practical information in this book, he suffers from not having had the opportunity of working in an orthoptic clinic of a hospital where in-patient surgical treatment is available, and where the full medical aspect of the case can be assessed. In consequence he neglects to evaluate the help obtainable from surgical treatment in cases of strabismus. This is exemplified by the statement made on page 195 with regard to the treatment of concomitant convergent strabismus in children, which reads: "... where the squint is alternating, and vision equal in both eyes, the squint can be safely left providing due care and attention are paid to the refractive error. The patient reports periodically for observation, but as a rule no orthoptic training is given until the child can appreciate what is meant by mental effort." Meanwhile the child labours under the adverse psychological effect of his physical deformity, and all the time is consolidating the secondary sensory and motor correspondences, which later will be difficult, or perhaps impossible, to eradicate. In the case of squint, as in any other physical deformity, an attempt should surely be made to cure the condition forthwith, not only cosmetically but also functionally. There is no doubt, therefore, that early operation is indicated in a large number of cases.

The chapter entitled "The Selection of Orthoptic Cases of Strabismus", which incidentally would be better entitled "The Selection of Cases of Strabismus for Orthoptic Treatment", is good, and clearly set out. The section of the book describing treatment is in the main good, and it is refreshing to find that Mr. Giles does not suffer, as so many orthoptists do, from being too synoptophore-minded, but appreciates the value of simpler forms of apparatus.

While realizing that ocular palsies are outside the scope of the book, the author has included two misleading diagrams (fig. 16, 21) which are intended to show the actions of the extrinsic ocular muscles. One would have thought that by now it was universally recognized that although the vertically acting recti muscles are adductors, they produce their maximum vertical action when the eye is in the abducted position. Similarly, although the obliques are abductors, they can produce their maximum vertical action only when the eye is adducted. It is the old story of one author copying another author's diagram without due consideration as to its veracity.

The statement on page 68 to the effect that "... it is rare" (in cases of ocular palsy) "to find only one muscle affected ..." probably indicates a lack of appreciation of the sequelae that take place following palsy of a single extrinsic ocular muscle, i.e., overaction of the contra-lateral synergist, contracture of the direct antagonist, and secondary inhibitional palsy of the contra-lateral antagonist.

The value of mental effort in the treatment of strabismus is undisputed, but one would have preferred to see photographs (fig. 35) that purport to show the effect of mental effort in a case of convergent strabismus explained on a physiological rather than a psychological basis, i.e., that when the eyes are elevated and accommodation relaxed the visual axes tend to diverge.

Fig. 36 is misleading. In the left-hand photograph the patient is clearly looking to the left, whereas in the right-hand photograph he is looking into the distance. One doubts if there is actually any difference in the angle of deviation shown in the two pictures!

The best part of the book is the practical advice given with regard to the use of the various instruments in orthoptic work. The author is to be congratulated on his handling of the subject, and also on the excellent bibliography. He has obviously taken an immense amount of trouble in the preparation of this book and has included interesting information on orthoptic treatment of candidates for flying duties, and on naturopathic methods of treatment. This is certainly a book that should be read by anyone who practises or who is interested in orthoptics.

T. Keith Lyle

## 1367 Modern Trends in Ophthalmology. Volume II

Edited by Arnold Sorsby. London: Butterworth & Co. Ltd., 1948. xix + 600 pages; 169 figures; 3 plates. 25 x 17 cm. £3 3s. [£1.15]

Section I. Physiology. (i) The nature of light; (ii) illumination; (iii) night vision; (iv) the electrophysiology of the retina; (v) antagonism and interaction in vision; (vi) senescence of the eye; (vii) mucopolysaccharides and mucoids of ocular tissues and their enzymatic hydrolysis; (viii) some subjective aspects of accommodation; (ix) variations and correlations of the optical components of the eye; (x) X-ray measurement of the diameters of the living eye. Section II. Diagnostic procedures. (xi) Contributions of the slit-lamp (biomicroscope) in the elucidations of clinical entities; (xii) gonioscopy; (xiii) angioscotometry; (xiv) ophthalmodynamometry and some of its clinical applications. Section III. Pathology. (xv) The nature of sporadic congenital malformations; (xvi) some genetic aspects; (xvii) ocular manifestations of vitamin deficiencies; (xviii) clinical lesions due to radiant energy; (xix) focal infection (1); (xx) focal infection (2); (xxi) virus affections of the eye; (xxii) some newly defined clinical entities affecting the conjunctiva; (xxiii) affections of the retinal veins; (xxiv) retinal and choroidal tumours; (xxv) abnormal pupillary reactions; (xxvi) lesions of the retina and optic nerve in association with blood dyscrasias; (xxvii) hereditary optic atrophy as a manifestation of the heredo-ataxias; (xxviii) detachment of the retina; (xxix) the pathogenesis of visual disturbances in glaucoma; (xxx) hypertensive retinopathy. Section IV. Treatment. (xxxi) X-ray and Grenz-ray treatment in ophthalmology; (xxxii) radiotherapy in ophthalmology; (xxxiii) sulphonamide therapy; (xxxiv) penicillin; (xxxv) the scope of retrobulbar alcohol injection; (xxxvi) orthoptics; (xxxvii) contact lenses; (xxxviii) ophthalmic ointments; (xxxix) trends in cataract surgery; (xl) the surgery of non-magnetizable intra-ocular foreign bodies; (xli) the blocked naso-lacrimal duct; (xlii) lessons from modern warfare (1); (xliiii) lessons from modern warfare (2); (xliv) amniotic membrane grafts in burns. Section V. Social aspects. (xlv) Some problems of industrial ophthalmology; (xlvi) the ocular manifestations of leptospirosis; (xlvii) some ocular aspects of aviation; (xlviii) the care of the blind in England and Wales. Index.

The purpose of the volumes in this series is to provide for the clinician who wishes to keep abreast of the most recent developments in his specialty a conspectus of that field of knowledge intermediate between the systematized information of the textbook and the latest scientific research reported disjointedly and only too copiously in current periodical literature. It is their aim to indicate "emergent tendencies and formative influences."

To this end 48 chapters have been contributed by 44 authors, drawn from most of the countries of Europe and America. Their wide range of subjects can be seen from the list of contents given at the head of this review. The volume ends with four chapters on social aspects, one of which discusses some problems of industrial ophthalmology, while another deals with the care of the blind in England and Wales.

It would be invidious, not to say presumptuous, to attempt to assess the comparative worth of individual contributions. All are interesting and, since they contain new knowledge, valuable. Time will, as always, show that some of the trends are towards blind alleys, and some of the new knowledge it will assess as worthy only of a brief note in the dustiest of archives. It is, however, works of this type which help the clinician to keep in advance, as he should, of the teaching of the textbook, and it is to be hoped that the two volumes already published will be followed by others at regular, and not too long, intervals.

The book is well produced and seems to have been most ably and impartially edited; not only have the professed aims of exclusion of the well-established and inclusion of new points of view been consistently achieved, but the various chapters are all equally, and eminently, readable. There is a good index and most of the chapters carry short but adequate bibliographies as the starting points of more extensive reading in any particular subject. The book is most useful in giving a short outline of recent progress and in indicating some of the lines along which further developments in ophthalmology will take place.

A. J. B. Goldsmith

## 1368 Clinical Ophthalmology for General Practitioners and Students

H. M. Traquair. London: Henry Kimpton, 1948. xii + 264 pages; 64 figures; 8 plates. 22 x 14 cm. £1 5s. [£1.25]

(i) Anatomy; (ii) physiology, including physiological optics; (iii) diagnosis; (iv) examination of the eye; (v) abnormalities in the pupils; (vi) causation of eye affections; (vii) therapeutics; (viii) refractive errors and their symptoms; (ix) squint, concomitant; (x) squint, paralytic; (xi) eyelids; (xii) lacrimal apparatus; (xiii) orbit; (xiv) the conjunctiva and the red eye; (xv) cornea; (xvi) sclera; (xvii) iris and ciliary body; (xviii) glaucoma; (xix) lens; (xx) visual path and field of vision; (xxi) impairment of sight without obvious external signs; (xxii) eye changes in some diseases of the nervous system; (xxiii) eye changes in some systemic diseases; (xxiv) functional ocular manifestations; (xxv) the eye in infancy and childhood; (xxvi) the eye in old age; (xxvii) misconceptions and prejudices. Appendix. Medico-legal reports. Formulary. Index.

This book has been written for the undergraduate and the general practitioner but it deserves the attention of a wider public.

Its language is simple and its teaching essentially practical. The eye conditions commonly met in everyday practice are dealt with concisely, but with relatively full notes on treatment which can be done without specialist knowledge and equipment. In this connexion one would say that more is expected of the general practitioner north than south of the Border.

There are excellent chapters on the routine examination of the eye, the meaning and significance of refractive errors and squints, therapeutic measures, visual fields, functional ocular manifestations and on misconceptions and prejudices. The chapter on impairment of sight without external signs, and some other parts of the book, are hampered by the intentional avoidance of the use of the ophthalmoscope, although one might say that the author has unintentionally shown such an avoidance to be an impossibility. There is little else to criticize, but one would contend that an acutely glaucomatous eye is not necessarily a red eye.

The book is most readable and its chief virtues are its wisdom and common sense. These alone should commend it to all who practise ophthalmology.

A. Lister

## PSYCHOLOGICAL MEDICINE

### 1369 Clinical Psychology. A Case Book of the Neuroses and their Treatment

Charles Berg. London: George Allen & Unwin Ltd., 1948. vi + 503 pages. 22 x 14 cm. £1 5s. [£1.25]

Section I. From medicine to mind. Section II. The problem of anxiety. Section III. The hysterics. Section IV. Some more severe illnesses. Section V. Treatment. Glossary. Index.

Dr. Berg is a provocative but extremely readable and lucid writer. Even the title of his book arouses criticism, as it does not fulfil the reader's hopes of learning something of the contribution made by the various schools of psychology towards our understanding of clinical problems; they are summarily dismissed as "academic", and clinical psychology is equated with psychoanalysis and its derivatives. The book's sub-title, "A case book of the neuroses and their treatment", would appear to be more representative of its contents; the writer develops his ideas on etiology, psychopathology, and treatment by means of varied and vivid accounts of his patients and their disorders. By his manner of presentation even more than by what he actually says, Dr. Berg pours scorn not only on physical forms of psychiatric treatment, but also on superficial methods of therapy ranging from simple advice and social management to unorthodox analytical approach and group therapy. And yet, later on, he acknowledges the improvements produced by these immediately practicable therapeutic approaches and the limited applicability of the one and only method, psychoanalysis, thought capable of producing a genuine cure of the basic disorder. At the same time, he condemns orthodox Freudianism, and sides with those analysts who believe that on the basis of the principal foundations laid by Freud a variety of structures may develop.

Dr. Berg's illustrative records of the histories and more important phases of treatment are particularly convincing, because only rarely is the patient 'cured' and the limitations of any form of treatment in psychiatry are shown up clearly; he states that psychotherapy can produce a limited, but in some cases very useful amelioration of the patient's symptoms by bringing into

consciousness emotionally significant contents of his childhood and infancy; beyond this, and far more important than environmental traumata, lies the patient's constitution as inherited at conception, and thus outside the reach of psychotherapy.

The first part of the book contains a description and discussion of various functional disorders from the dynamic point of view. Anxiety, or more fundamentally sexual tension, is looked upon as the prime mover in producing nervous or mental breakdown. Normally, these tensions obtain adequate discharge along instinctual or sublimated paths; but should they not gain this outlet, a morbid condition arises, finally leading to a violent bursting forth in the form of psychiatric symptoms. The resulting clinical picture is thought to depend on the physical and psychical structure of the individual. Following Reich, the author draws a parallel between nervous breakdown and sexual orgasm, and compulsive overwork is looked upon as the tumescent phase of a process of which nervous breakdown is its detumescence. For the causation of the more serious illnesses, including schizophrenia, etiological theories are put forward along familiar psychoanalytic lines, with the addition that Berg is a neo-Lamarckian and favours the view that morbid reaction tendencies as acquired by successive generations are transmitted, and can finally produce overt psychotics. In the second part of his book Dr. Berg discusses the various types of psychiatric treatment, giving a particularly clear account of the theory and practice of psychoanalysis.

Dr. Berg's book should be of great interest to general practitioners as well as psychiatrists who wish to acquaint themselves with the views on the theory and practice of psychological medicine arrived at by a widely experienced, psychoanalytically orientated, psychiatrist.

Felix Past

### 1370 *The Psychology of Behavior Disorders: a Biosocial Interpretation*

Norman Cameron. Cambridge, Mass.: Houghton Mifflin Company, 1947. xxi + 622 pages; 2 figures. 22 x 15 cm. £1 5s. [£1.25]

(i) Introduction; (ii) personality development and behavior disorders; (iii) behavior organization and behavior pathology; (iv) language, thought and role-taking in behavior disorders; (v) need, frustration, and conflict; (vi) basic adjustive techniques; (vii) hypochondriacal disorders; (viii) fatigue syndromes; (ix) anxiety disorders; (x) compulsive disorders; (xi) hysterical disorders; (xii) hysterical disorders: autonomy; (xiii) delusions and hallucinations in behavior disorders; (xiv) paranoid disorders; (xv) schizophrenic disorders; (xvi) manic and depressive disorders; (xvii) behavior disorders and cerebral incompetence; (xviii) therapy as biosocial behavior. Index.

This book is an attempt to produce an essentially social interpretation of all disorders of behaviour. Today man is regarded as a psycho-socio-biological unit, and understanding of human behaviour necessitates an approach from all these three aspects. Just as any attempt to explain man's behaviour purely in terms of anatomy and physiology has so far failed and is likely to continue to fail, so will attempts to explain it entirely in social terms.

On the other hand, *The psychology of behavior disorders* contains much that is refreshing and illuminating. It applies normal academic psychology and attempts to show that abnormal behaviour is merely an exaggeration of certain aspects of the normal. Although frequently impressed by the verbal arguments put forward, one was nearly always left with a feeling of "why?" Much of the work is descriptive rather than dynamic-interpretative. Wide use is made of the concept of functional autonomy of motive. This may supply a superficial explanation of behaviour, but frequently one is left to wonder why such behaviour ever arose; and even if an adequate explanation of this point is given, there is none as to why it then became autonomous.

No real notice is taken in the book of constitutional differences, and the biological side is regarded as a fixed element which can therefore be ignored. Individual differences of reaction to the same social stresses are inadequately explained.

Psychoanalytic theory is no less ignored than the biological aspect of man. The concept of the unconscious is rejected as an unnecessary hypothesis. We are returned, at least in part, to "behaviourism". Many psychoanalytic concepts, however, are used. This applies particularly to the chapter, "Basic Adjustive Techniques." Terms like "repression" and "regression" have by now a fairly well-established meaning in psychopathology

owing to their use and elaboration by the psychoanalysts. They are defined in this book in the accepted way, but the dynamics of these defence measures as previously elaborated by others are rejected. The new explanations given here do not appear to be an improvement, even if one disagrees with earlier explanations.

The description of the various behaviour disorders is reasonably accurate, although there are many points here and there on which psychiatrists will tend to disagree with the author. The definition given of "agitated depression" states that it occurs "... without serious behavior disorganization..." This is a dogmatic statement which many would see fit to challenge.

As a whole the book is not without interest; the earlier chapters are perhaps the best. Theory has to be stretched at times, when it is applied to the psychoses. Social theory will give, as would be expected, a partial, but never a whole, explanation of behaviour.

In spite of its verbosity, this book can be recommended, if only as the expression of an extremist's point of view.

R. Orton

### 1371 *Clinical Studies in Psychopathology. A Contribution to the Aetiology of Neurotic Illness*

Henry V. Dicks. Second edition. London: Edward Arnold & Co., 1947. 238 pages. 22 x 14 cm. 15s. [£0.75]

(i) Introduction; (ii) anxiety states; (iii) special forms of anxiety symptoms: phobias; (iv) obsessional states; (v) hysteria; (vi) the play of opposites; (vii) some perversions of sexual aim; (viii) abnormalities in sexual function; (ix) drug additions; (x) some general considerations and conclusion. Index.

This book originated from a series of lectures given to doctors and other students of psychopathology at the Tavistock Clinic, and presupposes in the reader comprehensive clinical experience of the psychoneuroses. Dr. Dicks describes himself as an eclectic in the field of psychopathology, who accepts the fundamentals of Freudian psychoanalysis, but who in common with other British psychotherapists has come to the conclusion that there are many clinical facts which do not fit in with psychoanalytic conceptions. The material on which the book is based was obtained during the treatment of patients, using a modified free-association technique with special stress laid on the working through of early childhood experiences. All the author's points are fully illustrated by case histories, and as far as this is at all possible, short of publishing complete treatment protocols, the accounts are lucid and convincing.

From the study of the psychopathology of anxiety states, obsessional states, hysteria, sexual perversions, and drug additions the author is led to postulate that there are three early and basic biological needs; apart from sexual tendency and aggressiveness corresponding to the libido and the death instinct of one stage in Freud's evolution of thought, he regards as more fundamental a "third instinct" of self-preservative tendency. This instinct of security is ultimately based in both sexes on the relationship to the good, protecting, nourishing mother. The element dread of loss of the mother expresses itself in infantile anxiety which, according to Dicks, constitutes the common denominator of all neuroses; the various neurotic syndromes are merely different ways in which infantile anxiety has been countered by various individuals. To give just one example: sexual perversions are not interpreted in the Freudian way as representing a failure to deal with impulses by reaction-formations; on the contrary, it is thought that many—though perhaps not all—types of sexual perversions in themselves represent reaction-formations against deeper feelings of deprivation and loss of the mother or the breast, and an attempt at recapturing them. From this follows that the therapeutic outlook on the perversions may not be as unpromising as has usually been thought. The aim and rationale of psychotherapy as practised by the author lies in the restoration of the sense of security for the fulfilment of the individual's emotional demands and needs. The analytic transference acts in the first instance by re-establishing this security, and this relationship between patient and therapist becomes the pattern for the development of mature personal relationships with his environment, i.e., the achievement of mental health.

The manner in which the author develops his theme and defines the position he takes up is instructive and thought-provoking, but his wholesale condemnation of the constitutional approach to almost all neurotic disorders will be regretted by readers who

remain convinced that there is such a thing as "neurotic constitution", but that nevertheless patients thus afflicted can be understood and helped along psychotherapeutic lines.

### 1372 Psychiatric Research

Cecil K. Drinker et al. Cambridge, Mass.: Harvard University Press; London: Geoffrey Cumberlege, Oxford University Press, 1947. (Harvard University Monographs in Medicine and Public Health, No. 9.) 113 pages; illustrations. 22 x 14 cm. 11s. 6d. [£0.575]

(i) Research at the McLean Hospital; (ii) biochemical problems related to psychiatry; (iii) integration of medical and psychiatric problems; a report of progress; (iv) protocol for a review of psychiatry; (v) psychical seizures; (vi) the psychobiology of psychiatric research.

In this stimulating little book are published six addresses given on the occasion of the opening of the new Laboratory for Biochemical Research at the McLean Hospital, Waverley, Massachusetts. The authors have described different aspects of psychiatric research, allowing themselves more freedom for speculation than they would, perhaps, in their more formal scientific communications. If this makes the book less commendable to the student, it enhances its interest to those who are already familiar with current trends in psychiatry.

The introductory address by Professor Drinker describes the historical development of the modern attitude towards psychiatry as well illustrated by the changes occurring in the mental hospitals of Massachusetts. "Research," he remarks, "is interminably expensive . . . yet, in the end, it has vast potentialities for profit . . ." The address of Dr. Jordi Folch, the Director of the new Biochemical Laboratory, gives a survey of brain function from the biochemical point of view. The chapter is outstanding and gives a masterful account of some of the main problems in this field. He describes in general terms the results of the work on the respiration and utilization of glucose by the brain, stressing the importance in this connexion of the blood-brain barrier. In describing the function of the glial cells he is prepared to credit the view that the astrocytes may function as "nurse cells" for the nourishment of the neurons, a suggestion which has found little acceptance among histologists, but which is nevertheless provocative and may lead to further work. The last part of his chapter is devoted to the biochemical aspects of the growth and development of the nervous system. Here he stresses the need for further research on the fundamental as well as on the clinical problems.

Professor Cobb's address deals with the etiology of neurocirculatory asthenia or "effort syndrome". Considering this as a particular problem in psychosomatic medicine, he emphasizes the importance of the "pluralistic" view of etiology; the factors concerned include those which are hereditary, anatomical, biochemical, and sociological, and are therefore best considered as a simultaneous assault by internist, physiologist, chemist, and psychologist."

Dr. Gasser points out that current developments of thought in philosophy are significant for neuropsychiatry, which needs to be looked at from a wider viewpoint than that from which it is often seen. He expresses the logical positivist thesis that many problems of science are mainly linguistic, involving the meaning and significance of statements. This is particularly relevant to psychiatry, in which too little attention has been given to the meaninglessness of statements which are incapable of verification. "The crucial question is, will not the science of psychiatry develop most rapidly if its reports are so phrased as to by-pass that for which there is no means of observation and subsequent communication."

Professor Wilder Penfield gives a fascinating account of our knowledge of the anatomical and electrophysiological factors related to psychical seizures. He concludes that further advance in psychiatry must depend on the development of the broad field of neurobiology, which includes all the basic sciences. Professor Strecker condemns the "all-or-nothing" attitude, which has led to the indiscriminate misuse of methods of limited application, such as electroshock treatment and prefrontal leucotomy. His essay is a plea for greater flexibility of thought in psychiatry.

It is refreshing to hear a group of distinguished investigators expressing their private views without restraint in terms which are intelligible to those who are not specialists. In a field which has never been dull, this volume provides new interest.

*Derek Richter*

### 1373 Introduction to Group-Analytic Psychotherapy. Studies in the Social Integration of Individuals and Groups

S. H. Foulkes. London: William Heinemann Medical Books Ltd., 1948. xiv + 181 pages. 22 x 14 cm. £1 1s. [£1.05]

Part I. General introduction. Part II. The background. Part III. The group-analytic situation. Part IV. The conductor's contribution. Part V. Survey. Bibliography. Index.

The name "group psychotherapy" is today applied to a variety of methods which cover an even wider range of possible techniques than is the case in individual psychotherapy. The term "group-analytic psychotherapy" has been coined by the author to characterize the distinctive features of his approach in contrast to inspirational, suggestive, didactic, or socio-dramatic group techniques. Group analysis shares with psychoanalysis basic psychopathological concepts. Yet there are essential differences which are stressed to prevent the misconception that group analysis is simply psychoanalysis in groups. The group situation contains therapeutic influences of its own which are not as immediate and actual in individual psychotherapy. The group approach may therefore be the method of choice for many patients.

The analytical group technique has the advantage of combining therapy with an opportunity for the scientific investigation of the mechanisms and forces operative within groups. The author's wide experience both as a Freudian analyst and as a group therapist enables him to make many relevant contributions to the numerous problems of group treatment, whether he discusses such apparently trivial, but nevertheless important, details as the size of groups and the seating arrangement of their members, or the changes produced in the patients' ego, or the specific therapeutic factors in group analysis. His principal object is, however, the exposition of the method of group-analytic psychotherapy, and, in particular, of the role of the therapist or "conductor" which he elaborates from many points of view. Without the conductor's influence the group would cease to be a therapeutic one. His task is therefore of first importance; it is described as "discriminating activity" which has to adjust itself flexibly to varying group conditions, and therefore may range from passive observation to subtle directing or even overt leadership at different times.

Examples of various group meetings illustrate the author's activities as conductor and his motives for them. To the reader, however, who has had no personal experience of the emotional response in therapeutic groups, the dry records of group conversations may appear flat and commonplace, as they fail to convey the living atmosphere—a difficult and perhaps impossible task.

The book is not entirely devoted to the description of analytic groups. Other groups of different size and purpose are described, to demonstrate the wider social implications of the group approach. This digression from the central theme recalls the author's experiences as an Army psychiatrist. He introduced the method of group-analytic psychotherapy at the Northfield Military Hospital, and later co-operated in what has since become known as the "Northfield experiment". This was a venture in hospital administration, based on broad principles of group co-ordination, which succeeded in bringing patients and staff together into a democratic and high morale hospital community of high morale.

The book would have gained if the author had applied more "discriminating activity" to his style of writing and composition which is often vague and diffuse. The unwary reader may miss many relevant thoughts which are obscured by their verbal wrappings.

*F. Kraupl Taylor*

### 1374 Modern Trends in Psychological Medicine 1948

Edited by Noel G. Harris. London: Butterworth & Co. Ltd., 1948. xii + 450 pages; 25 figures. 25 x 17 cm. £2 10s. [£2.5]

(i) The relation of psychological medicine to general medicine (psychosomatic medicine); (ii) the physiology of emotions; (iii) the importance of constitutional factors; (iv) the causative factors in mental disturbances; (v) electrophysiology in psychiatry; (vi) diagnostic measures; (vii) marriage and family life; (viii) the future of child guidance; (ix) psychopathic personality; (x) psychotherapy; (xi) recent technique of physical treatment and its results; (xii) further developments in abreaction; (xiii) modern social and group therapy;

(xiv) principles of mental hygiene; (xv) character formation in relation to education; (xvi) personnel selection; (xvii) mental hygiene in industry; (xviii) rehabilitation and the individual; (xix) psychological medicine and world affairs. Index.

*Modern trends in psychological medicine* is perhaps the most important symposium on mental health to appear since the special issue of the *Journal of Mental Science* published in 1944. In all, there are 19 chapters, each devoted to a separate topic, and each contributed by an author accepted as an authority in that particular field.

The articles cover a very wide range of subjects, from the physiology of the emotions to a study of psychological medicine and world affairs. One of the articles is contributed by a New Zealand worker, and two by Americans; the remaining 16 come from the United Kingdom.

It is one of the more satisfactory features of this symposium that an attempt has been made to cover work in progress in all parts of the United Kingdom. There is here no narrow limitation to the work of one particular school or of one particular region. All specialist workers in psychological medicine should find this book of interest.

G. A. W. A.

### 1375 Contributions to Psycho-Analysis, 1921-1945

Melanie Klein. London: Hogarth Press & Institute of Psycho-Analysis, 1948. (The International Psycho-Analytical Library, No. 34.) 416 pages. 22 x 14 cm. £1 ls. [£1.05]

(i) The development of a child (1921); (ii) the rôle of the school in the libidinal development of the child (1923); (iii) infant analysis (1923); (iv) a contribution to the psychogenesis of tics (1925); (v) the psychological principles of infant analysis (1926); (vi) symposium on child analysis (1927); (vii) criminal tendencies in normal children (1927); (viii) early stages of the Oedipus conflict (1928); (ix) personification in the play of children (1929); (x) infantile anxiety-situations reflected in a work of art and in the creative impulse (1929); (xi) the importance of symbol-formation in the development of the ego (1930); (xii) the psychotherapy of the psychoses (1930); (xiii) a contribution to the theory of intellectual inhibition (1931); (xiv) the early development of conscience in the child (1933); (xv) on criminality (1934); (xvi) a contribution to the psychogenesis of manic-depressive states (1935); (xvii) mourning and its relation to manic-depressive states (1940); (xviii) the Oedipus complex in the light of early anxieties (1945). Bibliography. List of patients. Index.

In the past twenty years two subjects have gained special prominence among psychoanalysts: psychological development during the earliest phases of infancy, and the manic-depressive and schizophrenic psychoses. To both subjects Melanie Klein, in London, has made original contributions. Now collected in a special volume, they give testimony to the author's devotion to psychological research and to the courage with which she has penetrated into a field of psychology where more stress has to be laid on hypotheses than on objective data. The author is convinced that certain mental processes in the infant's early life are identical with certain morbid mental changes encountered in psychotics. She writes of "the depressive position" of the infant child, of its flight from this into manic excitement, and of painful states perceived by the infant in the form of "persecution fantasies". From the changes in the infant's behaviour, which accompany its happiness and sadness, she believes she has learned how to picture "the inner world of the psychotic patient". Thus early mental development in its relation to psychological conflict and abnormalities in later life becomes for her full of meaning and dramatic possibilities. While these theories and observations are earnestly discussed among psychoanalysts, they have been definitely accepted only by those who have been working in close co-operation with the author. Without such contact familiarization with her approach seems impossible or, at least, difficult. The likelihood is not remote, however, that one day psychiatry will be able successfully to contact the psychotic, for his benefit, through what it has learned from the psychology of infants.

W. Hoffer

### 1376 Psychoanalysis Today

Edited by Sándor Lorand. London: Allen & Unwin Ltd., 1948. xvi + 404 pages. 22 x 14 cm. £1 5s. [£1.25]

(i) Freud's influence on medicine; (ii) psychoanalysis and internal medicine; (iii) psychosomatic medicine; (iv) therapeutic approach to psychosomatic problems; (v) child analysis; (vi) the early development of conscience in the

child; (vii) child-parent relationship; (viii) prevention of mental disease in childhood; (ix) juvenile delinquency; (x) psychoanalytic social work; (xi) mental hygiene; (xii) development of the ego-psychology; (xiii) dream mechanisms and interpretations; (xiv) sexuality and its rôle in the neuroses; (xv) hysterias and phobias; (xvi) obsessional neuroses; (xvii) character formation; (xviii) pathological character formation; (xix) war neurosis; (xx) neuroses and psychoses; (xxi) manic-depressive psychoses; (xxii) schizophrenias; (xxiii) organic psychoses; (xxiv) the technique of psychoanalytic therapy; (xxv) psychotherapy and psychoanalysis; (xxvi) the psychology of religion; (xxvii) psychoanalysis and sociology; (xxviii) problems of crime; (xxix) approaches to art; (xxx) psychoanalysis and literature (xxxi) psychoanalysis and anthropology. Index.

Some fifty years ago, in studying the phenomena of hysteria, Freud searched for a method which could replace hypnosis and lessen the physician's dependence on the patient's suggestibility. This book shows that since these early beginnings psychoanalysis has penetrated into every aspect of life, individual and social, healthy and morbid.

Not without justification has psychoanalysis been called the microscopy of the mind. Like interrogation of the patient in the state of hypnosis or like narco-analysis it can bring to consciousness—while not interfering with the state of consciousness itself—thoughts, feelings and memories which had been unconscious, of which the patient was not aware. Psychoanalysis possesses the revealing and at the same time frightening qualities of a microscope, which makes the invisible visible, be it structure, pathogenic agencies or morbid changes. Psychoanalysis not only reveals the modes of mental functioning, the intrinsic dangers which threaten our mental equilibrium, but also the healing power of insight into and awareness of those unconscious processes which are mainly centred round the memories which connect us with the past.

*Psychoanalysis today* is an atlas of such microscopy of the mind. Twenty-nine psychiatrists and psychologists have joined with the editor in his endeavour to present a comprehensive summary of psychoanalytic research and practice. Medical application plays a major part in this volume. It opens with four papers written by pioneers in the field of psychosomatic medicine. Special attention should be paid to those pages which describe the rôle of psychosomatic factors in the establishment of chronic disease patterns in patients who seek help while the illness is still reversible. This is an important aspect which balances the emphasis thrown on cure in contrast to the prevention of diseases.

Preventive measures are mainly discussed in the essays which depict the child's emotional development as it is encountered in child analysis, in the parent-child relationship and in mental diseases of childhood. Delinquency too plays an important rôle both from the curative and from the preventive point of view.

The psychiatrist will find a variety of papers dealing with such obtrusive factors of modern life as neuroses, perversions and character abnormalities. All the light psychoanalysis has been able to throw on to the understanding of the psychoses, including the "organic psychoses", is carefully recorded by renowned psychiatrists. No attempt is made to give instruction in the technique of treatment in detail, but two papers convey much information on therapy.

Modern medicine has now accepted the main concepts of psychoanalysis and is about to integrate them. Some misconceptions will still have to be rectified, and in doing so this volume will certainly be of great value. It is well adapted to add authoritative information to what the medical profession has learned about psychoanalysis from hearsay and sketchy teaching. But physicians should not be surprised if they find other professional groups equally keen to make use of psychoanalytic principles. They have been found most fruitful by educationists, social welfare workers, and scientists, who attempt to understand the origin of religious feelings and artistic creativeness, and especially in sociology and anthropology. While *Psychoanalysis today* has not been able to deal with all these applications, those which are presented are set forth in lucid and authoritative statements.

W. Hoffer

### 1377 Modern Psychiatry in Practice

W. Lindsay Neustatter. Second edition. London: J. & A. Churchill Ltd., 1948. viii + 275 pages. 21 x 14 cm. 12s. 6d. [£0.625]

Section I. Psychopathology. (i) Psychopathology—general; (ii) psychopathology—the different schools of thought. Section II. Disorders of children. (iii) Anxiety in children; (iv) behaviour disorders; (v) disorders of speech; (vi)

disorders of bladder and bowel control; (vii) mental deficiency; (viii) modern methods of treatment in children; (ix) vocational guidance (by Jack Jennings, B.A.). Section III. Neuroses and psychoses in adults. (x) Anxiety states; (xi) obsessional states; (xii) hysteria; (xiii) depressive states, mania and suicide; (xiv) psychopathy; (xv) paranoid states; (xvi) schizophrenia (dementia praecox); (xvii) the common organic psychoses; (xviii) abnormality of the endocrine system; (xix) abnormalities. I. Normal sexuality and dysfunction; (xx) abnormalities. II. Sexual malfunction (the perversions); (xxi) neuro-psychiatry and psychiatric sequelae [sic] of head injury. Section IV. Methods of treatment. (xxii) The approach to the patient; (xxiii) psychoanalysis; (xxiv) shorter psychotherapeutic methods; (xxv) physical therapy and comparisons of methods. Section V. General. (xxvi) Psychology and general medicine; (xxvii) causation and prophylaxis of mental illness; (xxviii) the law, and some problems of disposal. Index.

The first edition of this little introduction to clinical psychiatry was entitled *Modern psychology in practice* and was published in 1937. The present edition has been partly rewritten and reflects the author's further experience of civilian and service psychiatry. The section on psychiatric disorders of children is sensible and particularly helpful. There are new chapters on psychopathy, neuropsychiatry and on physical therapy. The whole constitutes a readable and entertaining account suitable for the general practitioner, nurse, social worker and schoolteacher. The medical student will be helped to a fuller understanding of both his psychiatric and non-psychiatric patients, and will be stimulated to further reading by the author's communicated enthusiasm. The views expressed are often unorthodox and so will not always commend themselves to examiners.

It has been Dr. Neustatter's aim to present his subject without recourse to technical jargon. His style is refreshingly original and light-hearted, but it is regrettable that his spelling and syntax must be similarly described. To those unfamiliar with the literature it will be irritating to read the names of authorities without any directions for tracing the relevant publications, and in a work for the uninitiated a list of references for further reading would be helpful. In the description of electro-convulsion therapy the stated voltage of 10 should read 100 volts.

H. G.

## RADIOACTIVE SUBSTANCES ACT

### 1378 Radioactive Substances Act, 1948. 11 & 12 Geo. 6. Ch. 37

London : His Majesty's Stationery Office, 1948. 12 pages. 24 x 15 cm. 4d. [£0.0165]

(i) Powers of Minister of Supply in relation to radioactive substances; (ii) control of importation and exportation of radioactive substances; (iii) control of sale and supply of radioactive substances; (iv) control of use of irradiating apparatus for therapeutic purposes; (v) safety regulations for occupations involving radioactive substances and irradiating apparatus; (vi) Advisory Committee; (vii) power of entry and inspection; (viii) offences and penalties; (ix) regulations and orders; (x) power to revoke or vary Orders in Council and orders; (xi) expenses of Ministers; (xii) interpretation; (xiii) application to Scotland; (xiv) application to Northern Ireland; (xv) short title.

The Radioactive Substances Act, 1948 establishes a most necessary control over the manufacture, sale and use of radioactive materials, and also over the use of irradiating apparatus "of a prescribed class or description" on human beings.

Power to produce, purchase, store, transport and dispose of radioactive substances is vested in the Minister of Supply under Sections 1 and 2. Section 3 of the Act is of the greatest interest to medical practitioners. Under it, the sale or supply of more than a certain quantity of any radioactive substance is forbidden when this is intended for therapeutic use on human beings unless by a qualified and specially licensed medical practitioner or by a registered pharmacist supplying "under the authority of a prescription signed and dated by any practitioner licensed as aforesaid". This restriction applies except in the case of a few specified exceptions.

The maximum quantities of different radioactive substances permitted to be sold freely will become known later in regulations made by the appropriate Minister after consultation with an Advisory Committee established under Section 6 of the Act. The licensing of practitioners under Section 3 is (in England and Wales) by the Minister of Health. Applications for licences must be made in writing to the Minister of Health within three months from a day to be appointed by the Minister. Until the practitioner is notified of the Minister's decision on the licence, the provisions of the Section will have effect as if the licence had been granted.

For the use of certain classes of irradiating apparatus on human patients, practitioners will have to be licensed under Section 4 of the Act. The types of irradiation apparatus are not specified in the Act, but they would no doubt include machines such as cyclotrons which can produce a stream of highly energetic ionizing particles.

Provision is made in Section 5 of the Act for the issue of regulations to protect from chance exposure to ionizing radiations persons employed where radioactive substances are produced, stored or used. The safe disposal of radioactive waste is also provided for. This is a problem which will become increasingly serious as the therapeutic use of radioisotopes is extended.

The Act is a well-thought-out and wise measure which should ensure that supplies of radioactive substances are readily available for use in research and medicine. At the same time, the public is safeguarded against avoidable exposure to ionizing radiation, and against commercial exploitation by the ignorant or the unscrupulous.

W. J. Arrol

## RADIOLOGY

### 1379 Modern Trends in Diagnostic Radiology

Edited by J. W. McLaren. London : Butterworth & Co. Ltd., 1948. xxi + 464 pages; 381 figures. 25 x 17 cm. £3

(i) Meaning of speed and contrast in X-ray materials; (ii) safety in the radio-diagnostic department; (iii) vision by X-rays; (iv) radiology in research; (v) radiographic diagnosis of tumours of the pharynx and larynx; (vi) occupational diseases of the lungs; (vii) pulmonary haemosiderosis; (viii) significance of segmental lesions in the lung; (ix) primary tumours of the lung; (x) the status of radiology in lung tuberculosis; (xi) post-operative chest complications; (xii) sarcoidosis; (xiii) radiology of the heart; (xiv) principles of kymography; (xv) modern trends in gastro-enterology; (xvi) colonic disease in children; (xvii) radiology of the gall-bladder; (xviii) renal tuberculosis; (xix) urethrocytography; (xx) tumours of bone; (xxi) vertebral disc lesions; (xxii) abnormalities of the spine; (xxiii) bone changes following irradiation; (xxiv) some aspects of ventriculography and encephalography; (xxv) cerebral angiography; (xxvi) the eye and radiology; (xxvii) foetal abnormalities (in utero and after birth); (xxviii) aspects of hydatid disease; (xxix) applications of diagnostic radiology in radiotherapy; (xxx) blood changes; (xxxi) the law relating to the practice of radiology. Index.

To keep constantly abreast of the progress of modern medicine is a difficult task. There have been so many recent advances in our knowledge of the causation of disease during the last ten years that to attempt to cover the whole field of medical literature would, however desirable, be an impossible task. In consequence one is apt to confine one's reading to one's own specialty and to neglect the wider sphere of general medicine. All workers in medicine have their own particular subjects in which they have accumulated a large store of knowledge, larger than the average worker, and to hear these views expressed in an authoritative article is more valuable than any review of the literature, however exhaustive that might be. To summarize these subjects in a small space will allow one to become conversant with all the modern work with the minimum of effort and yet leave a field for further research in the references provided by the author.

Dr. McLaren has accomplished this task in *Modern trends in diagnostic radiology*—the fourth book to be published in a series which has become extremely valuable and successful. He has not attempted to summarize the work of others, but has persuaded the authors to contribute exhaustive articles from their own store of knowledge; these he has collected together and edited. There can be no doubt that he has selected his authors with the greatest care and has persuaded them to say the maximum amount in as small a space as possible and to illustrate their articles well.

There is so much in the book that it is difficult to pick out any particular part for mention. The early chapters deal with technical problems, advantages and advances of the modern x-ray film, and the need and methods of providing adequate protection for workers in x-ray departments.

The editor himself contributes two sections to the book. The first is on the use to which x rays have been put in the field of research and the possibility of their extended use in the future, and the second on the indications and the value of examination by kymography. In the chapter on research he deals with the work which has been done with x-ray micrography in the study

of the circulation, and the value of x-ray cinematography. Articles follow on the soft-tissue radiography of the larynx and pharynx in the diagnosis and delineation of tumour masses. An excellent chapter on occupational diseases of the lung follows, in which the author enumerates and describes the conditions. He gives a warning about attempts to diagnose silicosis by the 35 mm. film. Further papers follow dealing with the early diagnosis of pulmonary tuberculosis by means of x ray and the evaluation of this method, the chest complications following surgery, and a very authoritative article on the subject of sarcoïdosis. All the papers cover the extent of our present knowledge and summarize the accepted views. There is a long paper on cardiac radiology which is particularly well illustrated and is of great interest. The modern methods of examination of the gastrointestinal tract are reviewed in relation to diseases of the stomach and bowel, with an exposition of modern views. Cerebral arteriography and the value of encephalography and ventriculography are fully dealt with; the latter paper, the last one to be published by Lysholm, deserves a high place of honour. The paper on the early diagnosis of renal tuberculosis is particularly valuable.

Papers are included on irradiation injuries and their detection, the legal implications of medical and radiological practice, bone tumours and the bone changes they cause, and the blood changes associated with the use of radiation. All these are valuable contributions of the highest order.

There is much to be said in praise of this book: it is excellently illustrated, well produced and bound, and the only criticism one can offer when reaching the end is that despite its 464 pages the book is still too short. Its reception will surely stimulate the author and the publishers to make the publication of a book of this type a yearly event.
